● Mr Enoch Powell used the debate to discuss once more his bill to protect human embryos. His argument was twofold. First, he failed to find any evidence, by correspondence with this journal, scientists and doctors, that any research of the kind that would be forbidden by his bill is actually being performed, arguing that his bill should therefore be passed. Second, he suggests that those who opposed his bill were the unwitting dupes of corporate giants that stand to gain by developing contraceptive and other drugs using human embryos as experimental material. Both these arguments, as well as the appropriateness of the issue in this debate, cut little ice **Maxine Clarke**

US agencies

NSF's hypothetical spree

Washington

THE idea of a federal Department of Science and Technology, which briefly resurfaced last winter for approximately the 100th time in the past 20 years, according to a tally by the Congressional Research Service, has appeared yet again, this time in a slightly veiled form. This week, the National Science Board, the governing body of the National Science Foundation (NSF), is to receive a study of what the agency would do if its budget were to increase by a factor of three over the next five fiscal years. The study, commissioned by NSF's director, Erich Bloch, included the assumption that as well as the extra money, NSF would take over the extramural research programmes of the Departments of Agriculture, Energy and Defense.

Although last winter's proposal rapidly fizzled out and while there is little chance that a budget-deficit-minded Congress would consider such a proposal even if it were submitted, the NSF study makes clear that those in high places would like a major reorganization of US science agencies.

One often-discussed idea, less drastic than consolidating all the science agencies into a single cabinet-level department, is a merger of NSF and the National Bureau of Standards, as proposed by the Reagan administration in 1983 as part of a plan to replace the Department of Commerce with a Department of International Trade and Industry. The proposal of last winter (in a study by the Presidential Commision on Industrial Competitiveness), took that as a starting point; the commission also considered adding in the research portions of the Department of Energy, the National Aeronautics and Space Administration and the National Oceanic and Atmospheric Administration.

Among the supporters of a cabinet-level department at that time was George Keyworth, the president's science adviser. And Roland Schmitt, the president of the National Science Board (and vice-president for corporate research and development at General Electric) said in a talk last winter at George Washington University that while he was unsure whether a Department of Science and Technology was the answer, the present organization of science agencies needed to be reexamined in the light of a failure to provide adequate support for the "science base" in the country. Schmitt said that NSF had traditionally supplied this base, which he said included the training of new scientists and engineers as well as research on new concepts too risky for industry to invest in, with help from the "mission agencies".

But now, he said, the mission agencies had become too involved with their missions to keep up their end "Maybe what we need is not a Department of Science and Technology but an NSF that is three times the size of the present one", said Schmitt.

Last week, however, NSF officials denied that the study ordered by Bloch was anything more than an "intellectual exercise" to identify research priorities and said that NSF had no wish to take over the research responsibilities of other agencies. **Stephen Budiansky**

Deep-sea diving

Japan finds clams and trouble

Tokyo

ON its second dive to the Tenryu Canyon off the Pacific coast of Japan, the French deep-sea submersible *Nautile* struck gold with the discovery of colonies of giant clams at a depth of 3,830 m, the deepest record so far of "vent communities" of organisms. But no sooner did news of the find break than *Nautile* sustained serious damage when surfacing in rough seas. Repairs to the submersible will probably take at least a month and may require the postponement of the Franco-Japanese project Kaiko until next year.

The colonies of clams were found on 6 June by Professor Claude Rangin of the University of Paris during a dive to the deep-sea fan at the mouth of the Tenryu Canyon, a steep-sided submarine valley that cuts into the accretion wedge of sediments being stacked up along the edge of the Eurasian plate as the subducting Philippine plate plunges beneath Japan. The giant clams are up to 15 cm in length and have been provisionally identified by Dr Suguru Ohta of the Ocean Research Institute, University of Tokyo, as *Calyptogena* sp , a genus of bivalve typical of the "vent communities" of organisms reported from mid-ocean spreading ridges and the subduction zone off the coast of Oregon.

According to Asahiko Taira, professor of sedimentology at the Ocean Research Institute, who made a dive to the clam site on 10 June, the colonies of *Calyptogena* sp. are circular, up to 60 cm in diameter and contain phenomenal densities of clams stacked on top of each other. One box core 250 cm^2 in cross-sectional area is said to have contained about 40 living clams, and during sampling some were crushed in the jaws of the box core releasing clouds of bright red blood. (The blood of vent organisms typically contains large amounts of haemoglobin.) On opening the box core on deck, a putrid smell was given off that made everyone feel sick, but hydrogen sulphide, which provides the "life-blood" of vent communities at spreading ridges, has not been found in anomalous amounts within the core and overlying waters, according to Dr Taira.

The colonies are aligned along north-east/south-west trending reverse faults associated with subduction and to a lesser extent along north/south strike-slip faults. The Tenryu Canyon runs along a major north/south transcurrent fault system which cuts into the mainland of Japan along the valley of the Tenryu River. Water inside the colonies shows positive thermal anomalies of a few tenths of a degree centigrade which may arise from connate water upwelling along the fault planes as the accretion prism of sediments flanking Japan is "squeezed" by subduction. The clam colonies thus in many rein the subduction zone off the Oregon/Washington coast, where it has been suggested that the vent organisms are powered by oxidation of methane contained in upwelling "old seawater" derived from underlying sediments (see *Nature* **313**, 339; 1985).

Other organisms found in the vicinity of the clam colonies include squat lobsters, gastropods, several of sea anemone and polychaete worms, but no giant tube worms have yet been found. Dr Ohta hopes to present the preliminary biological findings at an international symposium on deep-sea biology to be held in Hamburg, West Germany, next week. The specimens have been divided equally between the French and Japanese.

Cameramen from the Japanese national broadcasting corporation, NHK, will now be allowed to make two dives on the *Nautile* to film the seafloor. Japan's biologists, who have not been included in the dive schedule despite predictions that "vent communities" might be found (see *Nature* **313**; 1985), hope that NHK will choose to film the Tenryu Canyon clam colonies and perhaps collect some more specimens.

All this, however, depends upon *Nautile* being repaired in time to resume operations this summer. The electrical circuit of the submersible has been damaged and technicians and equipment must be flown out to Japan from France. At worst the Kaiko project may have to be delayed until next year, which could be a blessing in disguise as it would open a way for biologists to participate in the project. A decision on the future of Kaiko is expected this week. **David Swinbanks**

Soviet science

Gorbachev calls for new reform

ACADEMIC institutes in the Soviet Union must be "turned around sharply" to concentrate on research which is "technological in its thrust", the Soviet Party leader, Mikhail Gorbachev, told the Central Committee last week. Among other things, he proposed the establishment, within the Soviet Academy of Sciences, of "integrated, inter-industry scientific and technical centres".

This, in effect, would reverse Khrushchev's reform of almost 25 years ago, when its academy was stripped of its applied science institutes. Since 1976, party plans and directives have increasingly called for the academy to play a greater role in "coordinating" the implementation of research. Industrial centres of the type proposed by Gorbachev have already been established; one example is the Paton Electric Welding Institute under the aegis of the Ukrainian Academy of Sciences. This experience, Gorbachev suggested, should now be applied at the all-union level.

This turnabout would not, however, mean a decline of interest in pure research. On the contrary, said Gorbachev, it must be given priority, with no quarter given to "weakness" or "sluggishness". The research potential of the universities, in particular, must be better deployed. According to "available assessments", Gorbachev said, higher education establishments could increase the volume of their research by between 100 and 150 per cent (presumably without additional resources). Gorbachev's emphasis on the academy and university sectors is due, it appears, to the poor performance of the research establishments of the various production ministries. The Soviet Union spends 5 per cent of the national income on science, almost 90 per cent of that in ministry institutes More than half of all Soviet scientists work in them, and, according to Gorbachev, many of them, notably the Ministry of the Chemical Industry, have become "overgrown", with too many scientific institutes and pilot plants. Yet these are precisely the industries where there have been major shortcomings in developing new materials.

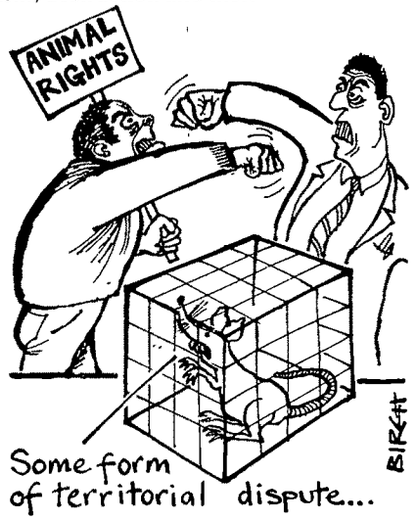
In his speech last week, Gorbachev complained that too many administrators, instead of finding a proper solution to a problem, shelve the issue by explaining that they are "carrying out an experiment", Gorbachev's answer is to strengthen the State Planning Committee, and to put into practice Lenin's dictum that the committee must be transformed into the country's "economic science organ, gathering together major scientists and leading specialists".

On the practical side, he urged that since the main weakness of Soviet industrial research lies in its isolation from production, many of the so-called "industrial" institutes should be immediately amalgamated with production enterprises. An immediate review should be carried out of how far the applied research institutes correspond to the current needs of industry.

Gorbachev also urged that something should be done about the declining prestige of engineers and the falling recruitment of talented young people into the technical sciences, which seems to have alarmed the Academy of Sciences. Gorbachev offers no immediate solution, but suggested that it may be time for a "serious reorganization" of higher education, meanwhile urging "measures to raise the social recognition" of engineers and technologists, including new pay deals.

Vera Rich

Animal rights



Battle joined on animal lib

Los Angeles

CALIFORNIAN investigators whose research animals have been stolen, whose laboratories have been vandalized, whose work has been disrupted and whose very lives have been threatened by "animal liberation" activists, are fighting back.

Earlier this month, several of them testified before a Californian Assembly committee on public safety which subsequently approved a bill that would stiffen the penalties for stealing research animals. An animal "liberator" currently faces misdemeanour charges, punishable by up to three months in county gaol and a fine, provided the animal is worth less than $400. The bill, if passed into law, would allow a judge to punish such a thief as a felon, with a 16-month to 3-year state prison term plus fines, no matter how inexpensive the animals.

"We are addressing the basic problem, which is interruption of research", says assemblyman William J. Filante, a northern Californian Republican who introduced the legislation. As the state legislature's only physician, Dr Filante said he feels an obligation to stiffen the penalties: "We are talking about vandalism, terrorism, destruction and theft".

Californian research facilities are threatened by ever bigger and bolder attacks, according to Sandra Bressler, executive director of the California Biomedical Research Foundation. The organization was set up last year, she says, to educate the public about how and why animals are used in biomedical research. California's leading universities, research clinics and other health organizations have joined the "fight back".

The problems began in 1982 when two monkeys used in brain research at the University of California (UC) at San Francisco were videotaped by interlopers. The tape was shown in Canada to raise money for animal rights groups. In 1983, two cats were stolen from a UC Berkeley campus psychology laboratory and twelve dogs used in cardiovascular research were taken from the Harbor-UCLA Medical Center in Los Angeles. The dogs, each valued at $5,000, wore pacemakers, research was delayed one year and the total loss was estimated to be £100,000.

In 1984, there were incidents of animal theft and vandalism at UC Sacramento and at the City of Hope Medical Center in Duarte. A $400,000 cancer study at Duarte was set back three years. There were also cases of threats and paint-spraying at UC Davis and San Diego.

In January this year, 11 rabbits were taken from a Napa county animal shelter and the chairman of the department of surgery at UC San Diego received a death threat. Two months later, the home and car of the Los Angeles county animal control director were vandalized. And in April 467 animals were stolen from laboratories at UC Riverside, ruining eleven projects and causing damage assessed at $683,000.

UC San Diego biology professor Mark Chappell lost 305 deer mice that he had painstakingly bred for five years to study variations in haemoglobin. Also in April, a student spirited away a cat being used to demonstrate premature infant resuscitation techniques at Stanford University.

None of the thieves, most of whom claim to belong to the Animal Liberation Front, has been caught, although there is one suspect from the Riverside incident and one person has been identified as passing on rabbits stolen from the City of Hope Medical Center.

The California legislature is under considerable pressure both from the biomedical community, which is powerful in California, and the animal rights activists, who are extremely vocal. Most legislators would like the problem to "go away", said an aide to Dr Filante. "But we expect it to stay a major issue for a long time. It'll be a big fight."

Sandra Blakeslee

Plant biotechnology

Young men go East to Georgia

Washington

THE University of Georgia, hoping to establish itself as a world-class centre for plant biotechnology, has acquired as a job lot a 20-strong research group from the University of Colorado. It has also committed $5 million over the next five years to establish 25 new faculty positions in molecular biology. The state of Georgia has demonstrated its support with a promise of $32 million for a new biotechnology building on the university's campus at Athens. The newly-hired research group is that of Peter Albersheim, who will be director of the new Center for Complex Carbohydrate Research. Albersheim let it be known last fall that he was planning to leave Colorado: Georgia was able to persuade him to Athens with an offer of almost 10,000 square feet of unused laboratory space in the Richard B. Russell Research Building, a facility of the US Department of Agriculture (USDA).

The new carbohydrate research group will work in collaboration with USDA scientists, and is expected to expand to a total staff of up to 40. Another reason Albersheim chose Georgia is the university's commitment to expand its biological research activities, which (including contract research) amounted to $75 million last year. About half of the promised 25 new faculty positions are likely to be in Albersheim's group, which brings with it from Colorado $1 million in research grants. Albersheim sees an impending golden age for the study of carbohydrates, which have tended to receive far less attention than other biopolymers. Now, he points out, it is becoming clear that carbohydrates, both individually and combined with proteins, play an important role in controlling metabolism and may dominate immunological reactions. Genetic engineering companies that have hitherto concentrated attention on proteins will in future have to pay more attention to carbohydrates, Albersheim believes. The University of Georgia has long nursed aspirations to be renowned for something. When president Fred Davison started looking at the available options, plant biotechnology seemed a likely choice.

It is planned that the faculty expansion over the next few years will be complemented by an international Information Center for Plant and Animal Biotechnology. This scheme, still rather vague, is intended to provide information to plant and animal breeders who may be aware of the potential of the new biotechnology but who do not know where to find researchers working in relevant areas.

According to Leon Dure, a professor of biochemistry at Georgia, there is a "distinct gap" in the knowledge of plant breeders about how recent developments might help their work. Dure expects that the member institutes of the World Bank's Consultative Group for International Agricultural Research, which includes crop and animal breeding centres all over the world, will be among the users of the new centre. In its initial phase the centre will concentrate on putting researchers and potential clients into contact with one another; later, it is hoped that more technical information, including gene and protein sequences and possibly complete scientific papers, will be included.

Tim Beardsley

Safety cabinets and AIDS

SIR — Many laboratory workers will be dismayed at the recent recommendation from the Advisory Committee on Dangerous Pathogens (ACDP) regarding the use of microbiological safety cabinets for the acquired immune deficiency syndrome (AIDS) agent human T-cell lymphotropic virus type III (HTLV-III). In this ACDP report[1] it is stated: "It is now clear that infection with HTLV-III may result in a fatal disease for which there is no effective prophylaxis or treatment. While there is still uncertainty about all the possible routes of transmission in the laboratory environment, care must be taken to avoid the dispersal of aerosols and for some work microbiological safety cabinets will be required. Because there are reservations about the level of operator protection which can be maintained by Class II cabinets under working conditions, for the time being, they must not be used for work with materials which contain the virus."

In many respects this conflicts with paragraph 5, Appendix A of the ACDP document *Categorisation of pathogens according to hazard and categories of containment* again published in 1984[2], only a few months before the AIDS recommendations. This appendix states that "In certain conditions some Class II cabinets will provide a protection factor of the same order as Class I cabinets (that is, a factor of 10^5 or better. BS 5726: 1979[3]).

If it can be shown by in-use tests that this level is achieved consistently (as demonstrated by tests carried out at regular intervals, the frequency of which will depend on use) and provided that the local safety arrangements will allow, a Class II cabinet may be used for some work with group 3 pathogens where protection of the work is essential. . . ."

In the six years since BS 5726 was published, many laboratories have invested heavily in both Class I and II cabinets that meet the operator protection requirements of the standard. Cabinet manufacturers have responded well to these requirements with the result that many open-fronted cabinets can consistently provide more than the minimum protection factor of 10^5. In addition, there has been a great improvement in the routine maintenance and certification of such cabinets. Many institutions now require certification to the filtration and containment requirements of the standard to be obtained twice per year for each cabinet.

The latest ACDP recommendations on the use of AIDS material in safety cabinets are questionable on two counts. In the first place they indict Class II cabinets in favour of Class I types and in so doing ignore the fact that Class I types are at least as easily disturbed by operator movements, by ventilation systems, by door movements and by people circulating within the laboratory. It is quite possible to reduce operator protection factors by one to two orders of magnitude by poor operator technique and lack of correct discipline.

Secondly, the recommendations totally disregard the current performance of many new Class II type cabinets which can produce consistent operator protection factors up to and beyond 10^6. It has to be remembered that BS 5726 makes no distinction between the operator protection of Class I and II cabinets – both must have factors of at least 10^5.

If there is so much uncertainty about the virulence of HTLV-III, then the very sensible procedures regarding the testing of operator protection factor initially outlined by ACDP for Class II cabinets[2] should be just as vigorously implemented for Class I types. As the weight of evidence does not favour transmission of HTLV by the airborne route, it is difficult to understand why Class I cabinets are allowed whilst similarly performing Class II cabinets are disallowed. Some of the work of this laboratory indicates that a number of the recently produced high performance Class II cabinets do, in fact, have higher nominal protection factors and are more resistant to disturbances than many Class I cabinets. Much of this cabinet evaluation work has been published in the scientific literature[5] and has formed the basis for containment policy in the Medical Research Council. It is naive to think that tissue culture work will always escape contamination in Class I cabinets or that they are intrinsically safer than Class II types. The banning of Class II cabinets by ACDP for AIDS work is inconsistent with their other recommendations and will cause grave difficulties for laboratory workers who require both operator and product protection without the difficulties associated with Class III cabinets. On this aspect of containment the ACDP committee should think again.

Life and death

SIR — Rapid innovations in the biological sciences and technology are creating new and difficult ethical problems, as is evident to readers of *Nature* from numerous articles and letters. Most prominent are problems concerned with the early phase of the human life cycle. (See for example recent letters to *Nature* on the question "When life begins", *Nature* **314**, 492; 1985.) The "rights" of a human zygote, embryo and fetus, but for some reason not gametes, seem to evoke strong emotions.

New problems are also arising about when life ends. Problems of organ exchange necessitate a legal definition of the death of an individual.

At another level, what should be the status of human cells cultivated *in vitro*? These cells, in common with zygotes, have the potential, theoretical at the moment, to be regenerated if properly nurtured.

Further problems are now raised with the news of cloning of DNA extracted from an Egyptian mummy (*Nature* **314**, 576 and 644; 1985).

The unique genome of a human being apparently does not die when a person stops breathing or when electrical brain activity ceases.

The DNA molecules can be extracted and under proper conditions can be replicated. Thus by at least some definition of living matter the DNA is "alive". If the DNA is still alive, should we not change our accepted procedures of disposing of human corpses?

I suggest that the procedure of cremation, sometimes associated with the saving of the ashes as a memorial, is improper. Instead it would make much more "biological sense" to save at least a sample of DNA from the deceased.

I envision "mausoleums" where sealed test tubes containing these DNA samples will be kept as an appropriate memorial to individuals. With the rapid progress of biotechnology, the potential for "resurrection" of at least some on one's traits is not remote.

Cows and goats

SIR — While Andrew Hill (*Nature* **315**, 222; 1985) shows deep understanding of the evolution of early African Hominoidea, his knowledge of Kalenjin nomenclature appears limited.

John Kimengich is surely John Kimngetich, which in Kalenjin means "born between 10 and 11 a.m. when the cows leave the cattle enclosure".

I am sure Dr Hill appreciates how in Kalenjin, as in English, omitting certain letters, for example the "o" from hominoid, can dramatically alter the sense.

Periodic extinctions undermined

Last year's fashion for explaining a supposed 16-million-year periodicity in mass extinctions of species has been made to seem a little spurious. Defining a mass extinction is a more urgent need.

THOSE who, last year, were enthusiastically speculating on the mechanism that might have been responsible for mass extinctions of living things at intervals of 26 million years will be given uncomfortable second thoughts by the article by Antoni Hoffman on p. 659 of this issue. For on the face of things, Hoffman has undermined the assumption on which all the excitement was based, the belief that there is a 26 million year periodicity to be explained But human nature being what it is, it seems unlikely that the enthusiasts for catastrophism will now abandon their quest

What Hoffman has done is to re-examine the palaeontological data on which rests the supposition that there is, or at least has been, a regularity in the timing of mass extinctions. The data consist of a catalogue of disappearances from the fossil record of families of marine animals compiled by J.J. Sepkoski and published, during 1982 and 1983, in the journal put out by the Milwaukee Public Museum. The first analysis of this material appeared in February 1984, in a paper by D.M. Raup and J J Sepkoski (*Proc. natn. Acad. Sci., U S A.* **81**, 801-5, 1984). It advanced the conclusion that mass extinctions of marine animals have taken place at times in the geological past separated by intervals of 26 million years or an integral multiple thereof

That Sepkoski's original data may not be robust enough to support this dramatic conclusion has always been a possibility, as Raup and Sepkoski themselves acknowledged The most obvious difficulty is the unavoidable uncertainty in assigning absolute ages to the successive geological stages recognizable only by the fossil assemblages that define them. For the past 100 million years, including the Cretaceous/Tertiary transition at 65 million years, the dating of the stages is reasonably good, with the result that most geological chronologies are consistent during that period, but disagreement is rife for earlier times. Raup and Sepkoski gave reasons, in their paper, for adopting the chronology due to W.B. Harland, the first column (labelled a) in Hoffman's Fig. 1 shows how the times of mass extinctions would have been changed if they had followed another equally plausible chronology

The nub of Hoffman's argument is, however, more subtle. Because palaeontological stages are defined by their fossil assemblages, each must differ from its predecessor and its successor by the appearance or the extinction of at least one family. So, Hoffman argues, distinguishing between a normal stage and one that qualifies as one of mass extinction requires the consistent application of some objective criterion He would prefer a criterion based on the rate or probability of extinction per unit time (say a million years) rather than one based on counting the number of family extinctions in a stage, which he says is biased towards periodicity.

So much is evident in the work of Raup and Sepkoski, where it is a necessary condition for associating a particular stage with a mass extinction that the number of families extinguished should be greater than in the preceding and succeeding stages. The effect of that is to exclude the possibility that consecutive stages could be associated with mass extinction, which is bound to prejudice the analysis towards a periodic interpretation Indeed, Hoffman argues, if the probabilities of extinction in successive stages are entirely independent, simply looking for peaks in the record of extinctions implies a one-in-four chance that any stage will be recognized as a time of mass extinction and, given the exclusion of the possibility that consecutive stages may be thus described, the analysis is certain to yield the conclusion that, on the average, extinction peaks occur every four stages. This, says Hoffman, is the origin of Raup and Sepkoski's periodicity.

The chief effect of this argument will be to emphasize how tricky is the concept of mass extinction. To be fair, many of the pitfalls were acknowledged by Raup and Sepkoski. The plain truth is that the disappearance of one or several families of genera from the fossil record cannot be counted as proof of a mass extinction, in the ordinary meaning of that term, without much more detailed scrutiny of the data than mere enumeration. How abrupt was the transition? Did all species disappear simultaneously, or can something be learned of the nature of the extinction from the sequence in which they disappeared? And since there are many possible causes of the extinction of species, genera and even whole families, ranging from evolutionary competition and climate change to external influences such as are involved in cometary or other impact, what can be said about the mechanism? The need to give at least partial answers to these questions should now be plain.

Where does this cautionary tale leave the explanations constructed to account for periodic extinctions, particularly for that which seems to have carried off the dinosaurs at the Cretaceous/Tertiary boundary? One conclusion that stands out from Hoffman's argument is what he calls the Maestrichtian stage at the end of the Cretaceous was, by all the different criteria applied, an extinction period.

Thanks to the work of the Alvarezes, father and son, and their associates, this is also recognizable by the world-wide presence of material rich in iridium at the physical boundary between the Cretaceous and the Tertiary The most compelling evidence that this material came from the impact of some extraterrestrial object with the Earth is the finding of cracks caused by explosion stresses in a high-pressure phase of quartz associated with the iridium layer (B. F. Bohor *et al. Science* **224**, 867–8; 1984). The case for this impact is strong (and would be even stronger if there were some trace of where it may have happened), but cautious people will insist that there is as yet only circumstantial evidence that the impact caused the extinction.

By contrast, the explanations of periodicity in the pattern of extinctions assume a somewhat academic character, which is not the same as saying they are uninteresting The most plausible source of material hitting the surface of the Earth is the distant ring of comets called the Oort cloud, from which material may be ejected towards the inner Solar System either by the perturbations of an unseen companion of the Sun (called Nemesis) or by perturbations of the Solar System caused by its periodic passage through the plane of the Galaxy.

Last year's rush of explanation has indeed thrown light on questions such as the stability of the Oort cloud, and of distant (and hypothetical) elements of the Solar System But the case for Nemesis has now wilted. And those who are attached to the notion that extinctions are caused by the oscillations of the Solar System above and below the plane of the Galaxy, among whom Clube and Napier (see *Nature* **283**, 455, 1979) seem to be the first, might now usefully turn the problem around, and ask what happens to the Solar System on these excursions through the galactic plane

John Maddox

Transgenic animals

New advances in the field

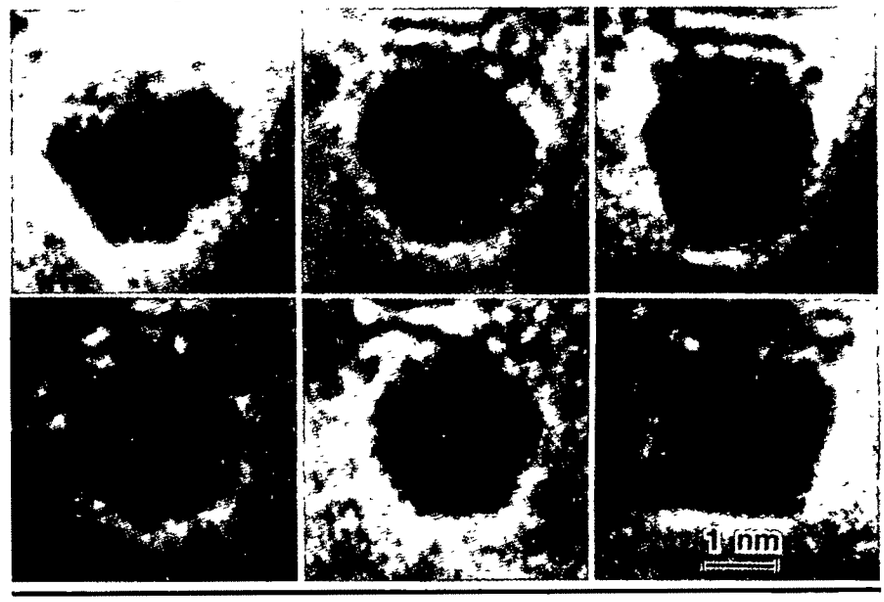
from Robin H Lovell-Badge

INJECTION of new genetic material into fertilized mouse eggs followed by development of the eggs into transgenic mice in foster mothers has become an almost routine tool in the analysis of a wide range of biological problems[1]. If the same technique could be used for farm animals it could be of great practical and economic importance, allowing the transfer of characteristics from one breed to another much more rapidly than by conventional breeding. More dramatically, it could allow genetic transfer between species. The paper by Hammer *et al.*[2] on page 608 of this issue is the first demonstration that it is indeed possible to use microinjection to obtain integration into the genome, and in some cases expression, of exogenous DNA in large mammals — namely rabbits, pigs and sheep.

To work with large domestic animals rather than mice requires a considerable investment, particularly in the number of animals required While it is normal to obtain up to 40 eggs from a single superovulated mouse, a ewe gives on average only three or four. Reimplantation of manipulated embryos may pose an even greater problem. Even though most will not survive, mice can tolerate up to 20 offspring, whereas sheep and cattle will not give birth to more than two. The occurrence of freemartins would be an additional problem with cattle.

These considerations have presumably influenced the selection of species used by Hammer *et al.* Pigs offer advantages because they are multiparous, sheep are an example of a difficult species and rabbits, while a reasonably convenient laboratory animal (and many a farmer's nightmare), are similar to pigs and sheep in many aspects of their early embryonic development. It is also essential to choose techniques that are efficient. It is clear from microinjection of tissue culture cells[3] and mouse embryos that transformation frequency is very low unless DNA is injected into the nucleus. But the eggs of many domestic animals have such an opaque cytoplasm that it is impossible to see their pronuclei or nuclei with conventional light microscopy. DNA-specific fluorochromes have been used to visualize nuclei in early bovine embryos[4], but the damage induced by ultraviolet light can severely compromise their development.

For sheep embryos, Hammer and colleagues have solved the problem to a large extent (but see below) simply by the use of interference contrast microscopy. More drastic procedures were necessary for the pig[5]. Centrifugation of the embryos at 15,000 *g* for three minutes separates the cytoplasm into three layers. Most droplets and granules, corresponding to the lowest buoyant density but greatest optical density, are found at one pole. The equatorial region contains a band of small clear droplets and the remaining half of the zygote has a translucent appearance. Nuclear structures may be found in either of these regions and are therefore clearly visible. The centrifugation of the pig embryos seems not to affect their subsequent development. It may also be a useful technique for other species, notably cattle, to allow experiments involving nuclear transfer for investigating the possibility of cloning[6], or parthenogenic development[7], of farm animals.



The gene chosen by Hammer *et al.* for injection into the nuclei of embryos of all three species is the mouse metallothionein–human growth hormone fusion gene that has been used in the same laboratory (Ralph Brinster's) for experiments with mice[8,9]. In each case about ten per cent of the injected embryos survived to term after reimplantation into foster mothers. The frequencies of fusion gene integration in the rabbit (12.8%) and pig (11.0%), although lower than the overall frequencies in mice (about 27%), are good, and other workers using these species will be much encouraged.

By contrast, the results with sheep are disappointing. Only one out of the 73 foetuses or newborn carried the injected fusion gene and even then it was obviously deleted or rearranged. It is conceivable that sheep embryos lack the appropriate mechanisms that fortuitously integrate exogenous DNA, but it seems more likely that some aspect of the technique needs refining. Perhaps more copies need to be injected and perhaps the visualization of the pronuclei needs to be improved (nuclear structures were not seen in a proportion of fertilized sheep eggs and these may correspond to more 'receptive' stages). Otherwise it may be necessary to adopt alternative strategies such as the use of retroviral gene vectors that are just beginning to work with mice.

Ovulation and fertilization are not v ry synchronous in the rabbit, pig and sheep, so it was necessary for Hammer *et al.* to inject embryos that ranged from 1-cell to 4-cell stages. For mice, even when the injections were at the pronuclear 1-cell stage, some of the transgenic animals were mosaic, presumably because gene integration was delayed. When this mosaicism was in the germline, few offspring inherited the introduced gene sequence[10].

Japanese gold in atomic motion

Use of a high-resolution electron mircoscope and video recorder has allowed the first real-time recordings of the motion of individual atoms. The pictures above show an ultra-fine particle of gold (18 Å across and containing about 500 atoms) photographed using the new technique by Sumio Iijima, a group leader in Japan's ERATO ultra-fine particles project (see *Nature* 305, 373; 1983). It can be seen that the shape of the particle changes over time, in discrete steps from top left to bottom right with all the gold atoms making up the ultra-fine particle moving cooperatively to form various crystalline structures. The gold atoms in ultra-fine particles thus seem to behave in a 'quasi-solid' manner with some properties like those of a liquid—one gold particle can even 'swallow-up' a smaller one. These phenomena await theoretical explanation.

It will be interesting to see if the same result emerges from breeding studies of the transgenic pigs and rabbits.

Expression of the fusion gene was observed in some of the transgenic rabbits and pigs, with a variation between individuals similar to that in mice and presumably due, at least in part, to different integration sites [8,9]. Further work will be necessary to show that the mouse metallothionein promoter works 'correctly' in rabbits and pigs, although it seems likely that the rules governing expression of exogenous genes in mice will be generally applicable to other mammals. Let us hope so, because it would be useful to derive transgenic mice to test the suitability of particular gene constructs before introducing them into farm animals.

It has long seemed likely that it would be possible to introduce genes into farm animals, and many groups around the world, often with considerable investment behind them, are attempting to do so. What are the potential gains? Some of the most obvious are improved efficiencies in reproductive performances and weight gain, increased disease resistance and changes in wool texture The introduction of extra growth hormone genes would be one way to increase growth but, although the results with mice have been dramatic [8], there has been no effect so far on pigs or rabbits[2]. It may be possible to produce transgenic animals with an increased rate of ovulation by, for example, increasing their gonadotrophin or lowering their oestrogen levels[11]. (Impaired fertility was an unexpected characteristic of some of the growth-hormone transgenic mice[12].) It may also be possible to increase ovulation rate with specific genes such as the *Booroolla* gene of sheep; the action of this gene is not entirely clear, but it may increase the sensitivity of granulosa cells to follicle stimulating hormone so that follicles mature when smaller[13] The association of specific histocompatibility antigens with particular diseases suggests that it may be possible to introduce non-associated alleles to induce resistance. Another possibility is the introduction of keratin genes to alter the properties of wool or hide.

Finally transgenic farm animals could be used to carry novel gene constructs as production systems for biologically and clinically important peptides and proteins. This should be particularly useful where expression in mammalian cells is required to give appropriate post-translational modification, or where the gene products are difficult to purify in other expression systems. It should, for example, be possible to use appropriate promoters to ensure that the introduced genes are expressed in the mammary glands of sheep or cattle, so that the gene products can be isolated from milk. Lest anyone should think this idea as silly as is that of converting the forelimbs of sheep into needles so they can knit, they should be aware that the use of silkworms for the production of interferon has just been reported[14]. □

Protein folding

. . . yet there is method in't

from Roger Pain

THE mechanism of protein folding has developed from a purely fundamental study into one which is also crucial to the recovery of proteins made by biotechnological means in microorganisms. While the patent literature shows that some degree of success can be achieved by empirical approaches, further improvements in the economy, scale and efficiency of protein recovery can be expected once the refolding pathway is better defined Since the rate at which folding occurs *in vivo* provides one of the major constraints on any theory, *in vitro* kinetics have been studied intensively. Much of this work has been centred on ribonuclease (RNase) and its progress has been followed in these columns[1–3]. But now there are some new twists to the tail

It is because its amino-terminal surface helix should constitute a revealing model for formation and association of a well defined element of secondary structure with a larger protein fragment that RNase has received so much attention. An added advantage is that one can compare RNase A, which is a single polypeptide chain, with RNase S, in which the helix, or "S-peptide", is associated with the remainder, or "S-protein", only by non-covalent forces following cleavage of the chain between residues 20 and 21.

Not surprisingly the observed kinetics of unfolding and refolding are frequently biphasic or more complex but, confusingly, such kinetics cannot be assigned to conformation changes alone. Brandts and colleagues have shown that the existence of at least two unfolded states, which contain different proline isomers and are indistinguishable by accessible spectroscopic techniques, would lead to multiphasic kinetics, even if the actual folding process were simple and monophasic[4]. In the absence of conformational constraints, proline distributes itself between the *cis* and *trans* isomers with half times of a few minutes; folding to a conformation requiring a unique isomer will result in biphasic kinetics from fast and slow refolding forms:

$$U_S \overset{\text{slow}}{\rightleftharpoons} U_F \overset{\text{fast}}{\rightleftharpoons} N \qquad (1)$$

where U_S and U_F are unfolded forms, and N is the native protein.

The characteristic feature of this theory is that proline isomerization occurs in the unfolded state. Subsequent experiments, initially from Baldwin's group, were interpreted as showing that proline isomerization can occur in a collapsed, partially-folded state I according to the scheme:

$$\begin{array}{ccccc} U_S & \rightleftharpoons & U_F & & \\ \uparrow\downarrow & & \uparrow\downarrow & & \\ I_1 & \rightleftharpoons & I_2 & \rightleftharpoons & N \end{array} \qquad (2)$$

where the intermediate form I_1 contains incorrect proline isomers and I_2 contains native proline isomers. In this sequential model, the slow phase of the kinetics arises from the existence of conformational intermediates as well as from proline isomerization[5]. It is further claimed by Baldwin's group[6] that isomerization can be speeded up in the condensed phase ($I_1 \rightleftharpoons I_2$). Schmid has suggested that an enzymically-active folded state, which he showed to be an intermediate on the folding pathway, contained an incorrect proline isomer[7].

Part of the difficulty in resolving these opposing views lies in the lack of methods which enable each intermediate to be fully characterized and each kinetic phase to be assigned to a particular molecular transition. While, for example, NMR has been used to follow the *cis-trans* isomerization in small peptides, it has not yet been successful in proteins In 1983, Brandts (with Lin) returned to the disputation with an elegant method for following the kinetics of proline isomerization: cleavage by certain proteinases of the bond between proline and its neighbour in a polypeptide is dependent upon the isomeric state of the proline, allowing the proportion of *cis* and *trans* isomers to be estimated as a function of time for a particular proline residue[8]. Lin and Brandts show that proline 93 is 100 per cent *cis* in native RNase A but only 70 per cent *cis* in the reversibly unfolded protein. Under refolding conditions, the relaxation time for isomerization from 70 per cent to 100 per cent *cis* is 90 s at 10°C Parallel measurements of regions of ribonuclease activity showed that 30 per cent of the activity is recovered in a slow phase with a relaxation time of

100 s The agreement of amplitude and rate shows that the slow phase in the recovery of activity is rate limited by the isomerization of proline 93, and argues for refolding taking place only from chains in which that proline is in the native *cis* form

Lin and Brandts have now studied two more of the four proline residues in ribonuclease Proline 117 is most probably completely *trans* in both native and unfolded states and therefore will make no contribution towards kinetic complexity. On the other hand proline 114 is completely *cis* in the native protein and 50 per cent *cis* in the reversibly unfolded state, which correlates with the low-amplitude slowest refolding phase This residue must be in the *cis* configuration for the protein to regain activity[9].

The major fastest phase of the refolding kinetics is thus unaccounted for and the isomerization of proline 42 has yet to be investigated — the experiments will be slow and tricky While Lin and Brandts are willing to acknowledge the existence of the non-native active intermediate their view is that, if it accounts for the major refolding phase, it is unlikely to involve proline isomerization. In support of this, they quote unpublished work of Fisher *et al.* This group has purified a new enzyme, peptidylprolyl-*cis, trans*-isomerase[10], which catalyses the kinetic steps associated (by Lin and Brandts) with isomerization of prolines 93 and 114 but has no effect on the major fast phase. Does this enzyme require the ribonuclease to be unfolded in order to catalyse the isomerization of proline, offering support for the Brandts model? To add to the confusion, Schmid, Buonocore and Baldwin[11] have not only further confirmed their sequential model but have also strengthened the evidence that the major phase shows the characteristics of proline isomerization.

On a slightly different tack, a further advance in assigning kinetic phases to distinct regions of the ribonuclease structure has come with the discovery by Labhardt that the S-peptide and S-protein fragments of RNase S can be distinguished by circular dichroism[12]. From the kinetics of conformational changes of both the S-peptide and the S-protein during their association and refolding reactions, Labhardt comes out firmly in support of a sequential type of folding pathway. Intriguingly, his experiments show that the S-protein folds (to a form as yet uncharacterized) in a fast phase before the S-peptide folds to its native helical structure. This fast phase corresponds to 65 per cent of the total change, greater than the proportion of fast folding species U_F in scheme 2. The folded form must correspond in part at least to I_1.

Since Labhardt has already shown that recombination between S-peptide and S-protein occurs fast and very early in the folding pathway of RNase S[13], we have to envisage, contrary to most previous expectations, that the association between these two regions occurs at a stage when the S-peptide, and possibly the S-protein, possess no native-like conformation This would be in keeping with the poorly hydrogen-bonded associated species detected by NMR[14]. If Labhardt's results, obtained with a relatively 'simple' system, are of general application, the model of 'flickering clusters' of secondary and super-secondary structure, which associate to be stabilized in the native conformation, will have to be considerably revised.

The circular dichroism results have also raised a problem relating to the unfolding kinetics. The unfolding rates for RNase S and S-protein, which have been followed by monitoring changes specifically in the S-protein moiety, parallel the formation of the *slowly* refolding species U_S which contains non-native proline isomers (scheme 2). The random isomerization of proline to form U_S had previously been thought to occur in the spectroscopically 'silent' reaction ($U_F \rightleftarrows U_S$) but Labhardt's results suggests that, in terms of the model of scheme 2, there must be a rate-limiting proline isomerization $I_2 \rightarrow I_1'$ which is faster than $I_2 \rightarrow U_F'$, followed by a rapid conformational unfolding $1_2 \rightarrow U_s$. Alternatively, the rate determining step is a conformational unfolding $I_2 \rightarrow U_F'$ followed by a rapid isomerization to U_S. Neither alternative fits easily with the expected relative rates of these processes.

The frustrating aspect of the whole question of proline isomerization is that, however the issue is resolved, it will tell us nothing about the actual *mechanism* of protein folding. Though it is becoming possible to see some of the detailed processes at work in the folding of ribonuclease, the methods have not yet overcome the kinetic madness of the system. □

100 years ago

AN excellent opportunity of observing the aerial means of propulsion in the flying fish was afforded me during a six days' calm lately when crossing the Bay of Bengal This must be my excuse for again touching this subject I watched day by day some hundreds rise under the bows of the ship The water surface was a glassy calm As each fish rose it spread its wings at once, apparently beating the surface with them two or three strokes before they steadied out. The tail which, of course, under water was in rapid motion, to escape from the ship, now gave ten or a dozen rapid beats, which could be counted by the ripples on the still surface, and the fish was off in aerial flight As each fish lost the impetus of the first rise, which generally happened at about forty yards, the binoculars showed us the anal fins, which had till now been fully extended, drooping to feel the water As soon as the surface was felt the tail was quickly introduced, and five or six smart strokes, also indicated by ripples, brought the impetus up again and carried the fish about another thirty yards, when another droop sent it on again, and so forth, some of the older fish travelling in this way 400 to 500 yards.

Astronomical spectroscopy

Interstellar space contains the largest encountered atoms

from William D Watson

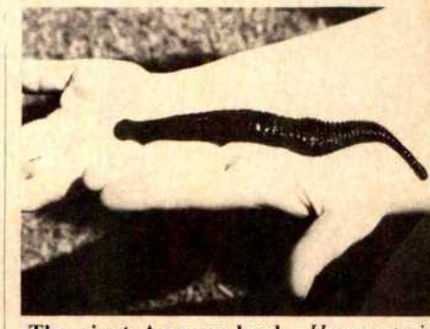
OBSERVATIONS published on page 647 of this issue[1], in conjunction with recent Soviet publications[2,3] highlight the presence of extremely high Rydberg states — in which the outer electron of an atom has been excited to very high energies — in the interstellar medium. These results confirm and significantly extend recent identifications[4,5] of spectral lines at radio frequencies an order of magnitude lower than those at which lines had previously been detected. Discoveries of new lines at radio wavelengths have until now tended to be associated with the high-frequency (millimetre and submillimetre) end of the spectrum.

Because of the appearance of several lines in the low-frequency series, it is clear that they result from radiative transitions involving extremely high Rydberg states (or radio-recombination lines) and changes of one unit in the principal quantum number of the state (alpha transitions). The lowest frequency at which these lines have been detected corresponds to the 732 alpha transition, which

indicates that the largest atoms that have yet been directly encountered in any environment are present (the radius of the Bohr orbit for a principal quantum number of 732 is 0.003 cm). These spectral lines are almost certainly due to atomic carbon.

There is evidence of pressure broadening in the new observational data. This phenomenon has not been detected previously at any wavelength in spectral lines associated with the interstellar gas clouds. Taken together for the first time, pressure broadening and the change from emission to absorption which is evident in recombination lines provide new diagnostic methods to delineate physical conditions of interstellar gas clouds. These clouds provide information about the process of star formation.

Radiofrequency transitions of atoms between adjacent or nearby Rydberg states with large principal quantum numbers have commonly been observed in astronomy since their first detection in the 1960s. Studies of these radio-recombination lines have had an impact on several astronomical issues[6] including, for example, the abundance of helium (which has cosmological importance) and the physical state of the star-forming gas (molecular cloud). They are observed primarily in the diffuse gas of our Galaxy, in either the hot, ionized gas of H II regions where lines of hydrogen and helium are seen or in the mostly neutral, cold gas of molecular clouds where the lines of carbon and sulphur are found. Before the prediction in 1959 by N. S. Kardashev that radio-recombination lines should be detectable, it was not appreciated that transitions between states with very high principal quantum numbers could be observed without overlap because of line broadening. High Rydberg states of atoms are also of interest to atomic physicists (see, for example, ref. 7).



Until recently, the principal quantum numbers of the radio-recombination lines ranged from about 40 to 300. As confirmed by the new observations, the range of principal quantum numbers that can be involved and the characteristics of observable transitions have been dramatically expanded. The current data substantiate the earlier proposal[4] that spectral features detected at frequencies near 26 MHz in the direction of Cassiopeia A by A. A. Konovalenko and L. G. Sodin[5] should be indentified as radio-recombination lines (alpha-transitions) involving the principal quantum numbers 630–640 of neutral atoms of an element other than hydrogen or helium. Except for these two elements, the isotope shifts are not large enough compared with the breadth of the lines to make a unique identification based on frequency alone. General considerations[4,8], as well as the association of these features with concentrations of neutral gas, strongly suggest that the atoms in question are carbon atoms. Carbon is the most abundant element for which the ionization potential is lower than that of atomic hydrogen. Thus, it can occur primarily as C^+ because of ionization by starlight in regions where hydrogen is in neutral form. The high Rydberg states involved in radio-recombination lines are populated primarily by the recombination of free electrons with the ions.

The recent observational studies[1–3] report the detection of the series of recombination lines far beyond the 26 MHz region described previously. In the direction of the radio source Cassiopeia A, the series is found to continue down to 16.7 MHz (732α) and up to 68 MHz (456α). Analogous, but more limited, sequences of such radio-recombination lines have now also been detected in several other directions in the Galaxy.

The idea of such 'large' atoms is, in itself, fascinating. As a result of the very weak binding of these Rydberg electrons, they interact strongly with their environment — that is other particles and radiation. One consequence is the observation of line breadths which exceed that due to Doppler broadening, the broadening presumably resulting from collisions with free electrons.

With increasing principal quantum number, the rate for collisionally induced transitions increases rapidly, whereas the loss rate from the Rydberg states due to spontaneous, radiative decays decreases at a comparable rate. The net effect is a greatly enhanced tendency for the excitation temperature of the very low-frequency recombination lines to approach the kinetic temperature of the gas. As a result, this new class of recombination lines has only been detected as absorption features in the spectrum of background, continuum radio emission. In contrast, at the lower principal quantum numbers ($\lesssim 300$) the populations of the states are expected to be inverted. Before the recent studies involving principal quantum numbers greater than about 450, radio-recombination lines had, in fact, always been detected as emission features. Thus, there is a change from emission to absorption that occurs with increasing principal quantum number. For alpha-transitions and representative physical conditions, the predicted transition tends to occur near 400 (ref. 8). The critical principal quantum numbers at which the change occurs do depend upon the physical conditions; hence, additional information for delineating the physical conditions of interstellar gas clouds can be obtained.

Although the first detection of pressure broadening and the change from emission to absorption by recombination lines are the most striking features of this new class of spectral lines, more detailed theoretical and observational studies may elucidate additional effects of diagnostic value for interstellar gas clouds. The relative importance of various physical effects associated with Rydberg atoms tends to increase rapidly with increasing principal quantum number. For example, pressure broadening by the free electrons increases approximately as the fifth power of the principal quantum number in certain relevant regimes. There is also evidence[2,3] that the strength of the lines is influenced by a resonance in the recombination[8,9] which is related to the fine-structure excitation of C^+. Rough assessments[4] of the expected strengths suggest that these recombination lines are likely to be widely observable in the gas of the Galaxy — a prediction tentatively supported by detections in several directions in the Galaxy other than towards Cassiopeia A. In the absence of a conveniently located compact source of continuum radiation, the diffuse synchrotron emission of the Galaxy is bright enough at the very low frequencies to provide an adequate continuum source against which the absorption can be observed. Finally, the occurrence of spectral lines at these very low frequencies provides a new opportunity for radiotelescope observers and investigators with an orientation towards very low frequencies. □

The giant Amazon leech, *Haementeria ghilianii*, which grows up to 0.5 metres in length. Its salivary gland secretes the specific fibrinolytic enzyme hementin and other biologically active substances of potential scientific and medical use. The gland provides a unique preparation for studying excitation–secretion coupling in single cells, because the cells are very large and are not electrically coupled; see the paper by P. G. Jones, R. T. Sawyer and M. S. Berry on page 679 of this issue.

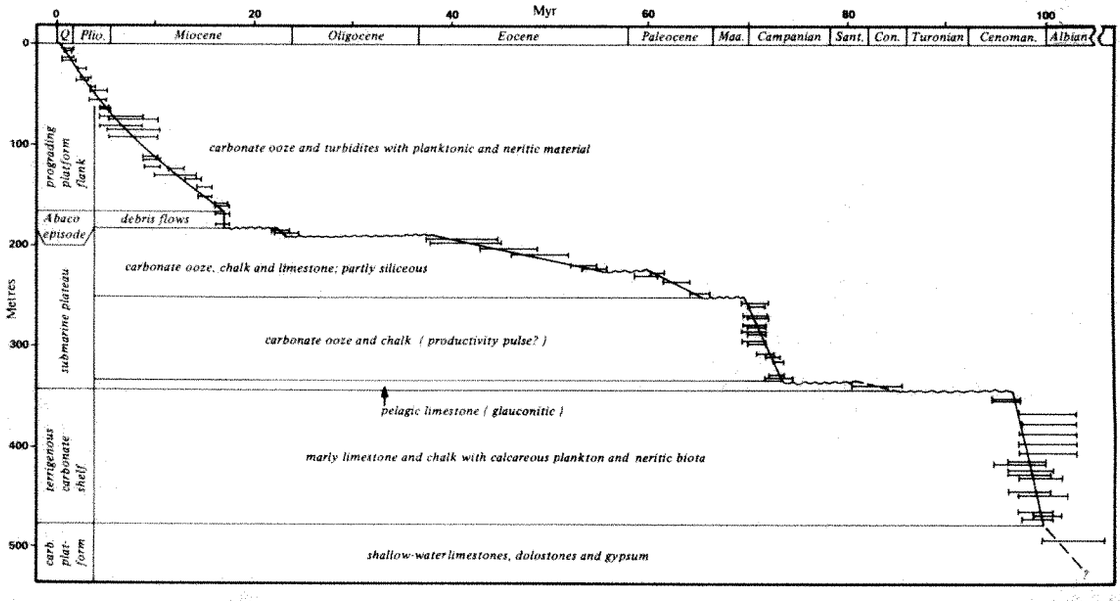
Ocean Drilling Program

Rise and fall of carbonate platforms in the Bahamas

*from the Leg 101 shipboard scientific party**

LEG 101, the first international voyage of the Ocean Drilling Project, began on 31 January, 1985 in Miami and ended there on 14 March after 11 sites had been drilled in the Bahamas archipelago. The decision to begin this new phase of deep-sea drilling with a study of carbonate platforms reflects the growing interest of earth scientists in the anatomy of large sedimentary bodies.

The drilling revolved around two themes: the origin of the present array of platforms and basins, and the study of platform flanks, their facies patterns and their response to sea-level fluctuations that entail flooding and exposure of the banks. The origin of Bahamian banks and basins continues to be the subject of intensive debate because the the pattern is unusual for passive ocean margins. In the past decade, the discussion has been governed by two fundamentally different concepts. One of them, the graben hypothesis, calls for strong fault control of the bank-and-basin pattern. It assumes that the present deep-water basins originated as grabens in the rift stage of the Atlantic and have remained topographic lows ever since[1]. On the other hand, the megabank hypothesis[2] assumes that rift structures and other inherited tectonic features were soon smothered by sediments during the spreading phase of the ocean and that for most of the Jurassic and the early Cretaceous, Florida, together with the northwestern Bahamas and northern Cuba, formed a single, flat-topped carbonate platform – the 'megabank'. In the Cretaceous, this platform gave way to the present array of banks and basins.



Debate continues in the wake of drilling. Most of us feel that Leg 101 and the preceding seismic-site surveys have greatly strengthened the megabank hypothesis. However, at least one of us (Mullins) considers the evidence inconclusive, mainly because we failed to reach the relevant seismic horizon in the Straits of Florida and Northeast Providence Channel, and prefers to emphasize that deepwater early Cretaceous sediments were recovered on Leg 77 of the Deep Sea Drilling Project, in dredge hauls from Samana[3], and also on this leg from site 635. On the basis of this evidence multiple bathyal environments may already have been established at that time.

Leg 101 recovered shallow-water carbonates and evaporites of the megabank under the southern Blake Plateau. In the Straits of Florida, the carbonate platform was not reached but a close stratigraphic tie was established with an exploration well on Great Bahama Bank, 60 km to the north-east. The continuity of seismic records between site 626 and the Great-Isaac 1 well strongly suggest that the entire Straits of Florida is underlain by a continuous carbonate platform. Furthermore, the two holes indicate that rather than remaining stationary since the Mid-Cretaceous, the margin of Great Bahamas Bank has alternately retreated and prograded tens of kilometres during the past 100 Myr. Blake Plateau and Little Bahama Bank display a similar rhythm of mid-Cretaceous drowning and retreat followed by Late Tertiary expansion of the platforms (see figure). The evidence for wide horizontal migration of the platform margins and for shallow water carbonates underneath some Bahamian basins is not easily reconciled with the graben hypothesis of the Bahamian troughs[2].

Mid-Cretaceous disintegration of the megabank does not seem to be related to local tectonic deformation but rather to a crisis in the depositional system. The drowning of the Bahama platform is part of a world-wide extinction of carbonate platforms that coincides with a tendency towards oxygen deficiency in the oceans[4]. Exploring links between anoxia and platform drowning remains one of the most challenging tasks for the shipboard party.

While for most of us the drilling tipped the balance in favour of the megabank-hypothesis, some modifications of that concept are called for. The stratigraphy of the Leg 101 sites, along with recent dredging results, indicates that mid-Cretaceous platform drowning was not synchronous throughout the archipelago and that it predates the mid-Cenomanian sea-level cycle of Vail *et al.*[5]. Drowning seems to have progressed in steps from the south eastern perimeter of the megabank to the centre. The oldest known deep-water sediments at the southeastern tip of Great Bahama Bank (Samana) are Neocomian in age[3]; 350 km farther northwest,at site 635, they are Albian; at site 627 and in the Great-Isaac 1 well, in the centre of the archipelago, they are Cenomanian in age.

Platform flanks were studied in two three-hole transects with the hydraulic piston corer. The response of platform flanks to sea-level fluctuations has recently become the focus of a lively discussion [6–8] and was one of the principal study objectives of Leg 101. Vail *et al.*[5] assume that sediment is fractionated between shelf and basin in only one way during a sea-level cycle: during high stands of sea level most sediment is trapped on the inner shelf; during low

Age versus depth profile and geological history of site 627 on the southern Blake Plateau. Drowning of the carbonate platform during the mid-Cretaceous crisis is followed by partly terrigenous deposition on a shelf, and by 80 Myr of slow pelagic deposition on a submarine plateau. In the past 20 Myr, the area has been influenced by the prograding Bahama platform again. "Abaco episode" is a wide spread incidence of debris flow deposition in the middle Miocene documented in the Blake Bahama-Basin DSLP Leg 44 (ref 9).

stands, when rivers carry their load right to the shelf edge, most material escapes to the deep sea. Results of Leg 101, along with a growing number of data on the late Pleistocene indicate that carbonate platforms do not fit this trend.

Preliminary comparisons of stratigraphy on the Bahama banks and in the basins strongly suggest that periods of low sea level (and bank exposure) 3 Myr BP and 5-6 Myr BP correspond to intervals of slow deposition and scarcity of turbidites in the basins. When sea level was high and the banks were flooded, sedimentation rates in the basins increased dramatically. This observation supports the concept of 'high-stand shedding' of platforms as opposed to the generally accepted phenomenon of 'low-stand shedding' of terrigenous continental margins.

The fine sediment exported by the platforms consists largely of aragonite, a form of calcium carbonate that is metastable in most burial environments and is rarely found in pre-Quaternary pelagic sediments. On the flanks of the platforms, bank-derived aragonite mixes with the remains of calcitic plankton. Leg 101 drilling provided the first glimpse of the burial history of this peculiar type of carbonate ooze The first-order trend shows a downhole decrease of aragonite and its replacement by calcite cement. Whereas calcite cementation is more rapid than in pelagic carbonate ooze, aragonite dissolution was found to be unexpectedly slow: 7 Myr-old limestones were found to contain 15–20 per cent aragonite. Superimposed on this first-order trend are cyclic variations in aragonite content. In the Quaternary, these have been shown to reflect climatic cycles. Further study of the Leg 101 cores is expected to reveal the Neogene climatic history of the platforms

Hydrocarbons were encountered at several sites and led to abandonment of two holes. Oil stains and wet gas were found in Cretaceous dolomites on southern Blake Plateau, and tar impregnations appeared in Miocene chalks in the Straits of Florida and in turbidites in Exuma Sound All these are interpreted as hydrocarbons that have migrated from deeper parts of the section. In accordance with ODP practice, these holes were plugged with cement.

Leg 101 has added a dimension of Earth history to the numerous studies on modern platform flanks. The modern sediments of the Bahamas, often used as a standard for the interpretation of the geological record, have provided the key to their own past. This part is more varied and turbulent than previously believed. Periods of crises and of rapid expansion figure prominently besides intervals of steady growth. These changes seem to be governed by a complex interplay of oceanic productivity, eustatic sea level and tectonics that we have barely begun to document and understand □

Astrochemistry

Aluminium clues to the formation of the Solar System

from Donald D Clayton

WHEN groups in Australia and at the California Institute of Technology first showed that aluminium-rich minerals from the Allende meteorite contained more ^{26}Mg than expected, it was argued that a supernova must have exploded beside the forming Solar System. The argument went that the explosion peppered the solar cloud, from which Allende formed, with the short-lived and radio-active ^{26}Al, and that the excess ^{26}Mg in the meterorite is the result of decay of ^{26}Al within the present meteoritic minerals. This conclusion has now been shaken by the detection of surprisingly large amounts of radioactive ^{26}Al in the interstellar medium. As a result, alternatives to both the theory of injection from an exploding supernova and the theory of decay within the actual meteorite are being seriously considered.

The original detection of ^{26}Al — the first ever detection of interstellar radioactivity—was made by the HEAO 3 spacecraft (Mahoney, W.A. *et al Astrophys J* **286**, 578; 1984) which recorded a measurable flux of 1,809 keV gamma rays striking the Solar System These rays are a well known electromagnetic radiations product of the beta decay of the ^{26}Al nucleus. HEAO 3 measured about 4.8 such gamma rays per square meter per second, coming from the general direction of the centre of our Galaxy, but at an unknown distance. Any lingering doubts about the reality of this astonishing discovery have since been removed by a gamma-ray spectrometer on board the Solar Maximum Mission satellite which, since February 1980, has taken unintentional periodic looks at our galactic centre The spectrometer team (Share, G. H. *et al.*, submitted to *Astrophysics J.*) confirm that there are about 40 gamma rays per square metre per second coming from the general direction of the galactic centre, so that it can now be asserted without reasonable doubt that a source of radioactive ^{26}Al lies in that general direction.

In an analysis of the magnitude of this gamma-ray flux and its implications for both the origin of the elements in explosions of stars and for the origin of the Allende minerals (Clayton, D. *Astrophys. J.* **280,** 144; 1984) I came to two unexpected conclusions. First, if the ^{26}Al is spread uniformly throughout the interstellar gas, its concentration of about 10 parts per million of aluminium is rather close to that provided by Allende minerals, suggesting that it is unnecessary to invoke the injection of ^{26}Al into the forming Solar System by a supernova trigger Second, supernova explosions are not adequate to maintain the average level of observed interstellar radioactivity, so that nova explosions or gas streaming away from giant stars are the more likely origins of the radioactive aluminium now found in the interstellar medium. This also argues against the presence of a special supernova trigger to Solar System formation. A.G W. Cameron, an early advocate of the supernova trigger theory, has given that idea up. He now argues (*Icarus* **60,** 416; 1984) that wind from an asymptotic giant branch star of about one solar mass carried ample ^{26}Al along with it and participated hydrodynamically in the formation of a molecular cloud core wherein the Sun formed A similar argument could be constructed with winds from Wolf–Rayet stars, which are also now expected to be enriched in fresh ^{26}Al (Dearborn, D. & Blake, J. *Astrophys J. Lett.* **288,** L21; 1985).

Interpretation of the excess ^{26}Mg in Allende aluminium-rich minerals depends on the correct interpretation of the ^{26}Al gamma-ray line, which requires better information on its angular distribution. Because of their wide viewing angles and serendipitous measurements, the HEAO 3 and Solar Maximum Mission teams have been reluctant to be very precise about the angular distribution. Although they describe it as being "consistent with" radioactivity concentrated in the galactic plane and with peak intensity near the galactic centre, they stop short of claiming that the data requires that interpretation

An alternative explanation invokes a

supernova explosion ten thousand years ago and about 20 parsecs from the Sun. This could happen to have been toward the general galactic centre, and would occupy a large circular area on the sky (perhaps a 30° – 90° cone). But it would be most unlikely that the centre would lie in the plane of the Galaxy. Only if the observing teams can successfully show that the latitude distribution is narrow and centered on the plane, will we be forced to accept the observed concentration of ^{26}Al as a general feature of the gas. In what follows, however, let us assume that the ^{26}Al is a general galactic feature rather than a local one.

At 10^{-5}, the interstellar ratio of ^{26}Al/^{27}Al lies squarely between, but distinct from the ratio of 5×10^{-5} for some, but not all, aluminium-rich Allende minerals and that of less than 10^{-6} could be maintained there by supernova explosions. The excess of ^{26}Al in Allende minerals is therefore still too large to be interpreted as being the average interstellar concentration. Thus, if the present ^{26}Al decayed in the present Allende minerals, there must have been some source of ^{26}Al enhancement in the solar cloud as it collapsed to form the Solar System. This is the reinterpretation that Cameron now advances.

There are, however, new doubts that the ^{26}Al was ever 'alive' in Allende, as I discussed at the 16th Lunar and Planetary Science Conference in Houston, during March 1985 Whatever objects serve as the source of the ^{26}Al currently observed by gamma radiation, they are necessarily ejecting $4M_\odot$ of it per million years into the interstellar medium. By contrast, supernova eject $24M_\odot$ of the new stable aluminium, and stars reinject $60M_\odot$ of old stable aluminium over the same million years. If all of these ejecta condense into refractory aluminium-rich solids as they leave their respective sources, and if the ^{26}Al decays to ^{26}Mg within the resulting mixture of well mixed dust grains, the ratio of ^{26}Al within the aluminium-rich interstellar dust will be 0.05, fully a thousand times greater than the correlation in the meteoric aluminium-rich minerals. This high interstellar correlation of excess ^{26}Mg to Al could not have been totally removed by evaporation, because the Allende minerals carry other isotopic anomalies that demonstrate that they were not evaporated totally at any stage prior to their assembly. Thus these arguments indicate that the ^{26}Mg–Al correlation observed in Allende minerals may be a manifestation of a cosmic chemical memory; the observed concentration of interstellar ^{26}Al necessarily creates such a large interstellar ^{26}Al anomaly that the special chemistry invoked for the ^{26}Mg daughter is no longer required by a fossil theory. The challenge now to mineral chemists is to demonstrate how this memory survives the process of the formation of minerals and the substantial extraction of magnesium from them. □

Nuclear war

Poor outlook for tropical weather

from A. Barrie Pittock

THE most important environmental effect of a major nuclear war in the Northern Hemisphere may be caused by reduced rainfall in the tropics and subtropics. This conclusion was reached at a recent conference* and will be incorporated in a report later this year (see *Nature* **315**, 534; 1985).

SCOPE (the Scientific Committee on Problems of the Environment) has run a series of scientific workshops, this being the first to be held in the Southern Hemisphere. New results from computer simulations were reviewed, incorporating explicit modelling of smoke dispersion from target areas in North America, Europe and the Soviet Union, and fully interactive smoke (that is, smoke that modifies the atmospheric temperature and wind structure and is then moved around by the modified circulation). This overcomes two of the major weaknesses of the earlier simulations, which assumed an initial uniform smoke distribution over Northern Hemisphere latitude zones and did not allow for smoke movements.

A common feature of the results from simulations performed by the three different laboratories in the United States (Los Alamos, Livermore National Laboratories and the National Center for Atmospheric Research) and in the Soviet Union, was that smoke was 'lofted' from its initial height of injection to around 10 to 20 km in altitude and then moved south, because of heating by absorption of solar radiation. This effect occurs only in the northern spring and summer seasons when the solar radiation is sufficient to cause the lofting to take place. In winter the smoke tends to move towards the Arctic and is more quickly removed.

This lofting effect and the increased stability of the lower atmosphere (which reduces precipitation) quickly separates the smoke from the washout processes in the spring and summer. Such results make it seem more likely that the smoke will last long enough and move far enough south to affect seriously the tropics and the Southern Hemisphere.

In mid-northern latitudes, full-blown nuclear winter effects will probably occur but, as this is the zone where most damage will be done by the direct effects of the nuclear explosions, this 'lofting' effect will be irrelevant. But as the smoke spreads southwards it will stop the solar heating of continental land surfaces that drives the south-west monsoon, halting the rainfall necessary for survival over most of southern and south-east Asia. This could be far more disastrous than temperature decreases in the tropics of 10 – 15°C, even though rice is particularly sensitive to this degree of cooling.

Further south, rainfall over mainland Australia is expected to decrease, initially because of strengthening of the descending arm of the Hadley Circulation in the southern sub-tropics, and later from a general decrease in the hydrological cycle. A pre-'nuclear winter' study by B. Hunt (*Mon. Weather Rev.* **81**, 3677; 1976), where an 18-level primitive equation model was run with the solar insolation turned off, showed a rapid decline in the water vapour content of both the atmosphere and the eddy kinetic energy (strength of the synoptic weather disturbances). As Australian agriculture is mostly limited by precipitation, this effect will have a major effect on productivity, whereas the relatively modest temperature reductions may be less serious. New Zealand and Tasmania, on the other hand, are further south, so temperature is more limiting and even modest cooling may significantly reduce production.

Australia, New Zealand and Argentina currently have food surpluses, so that even large reductions in production may not lead to mass starvation in these countries, unlike much of southern Africa and the tropics. Thus, the greatest impact of the 'nuclear winter effect' may result from reduced rainfall in the highly populated countries of Asia and Africa rather than in countries in the mid-northern latitudes.

Several major uncertainties have been given more adequate treatment in recent, as yet unpublished, work discussed during the workshop. Areas still to be investigated are the rates of smoke washout in the initial plume-rise phase, the optical properties of aged smoke (especially at infrared wavelengths) and the possible smoke removal processes in the stratosphere. Better knowledge of effects on the Southern Hemisphere also requires computer simulations to be run for longer periods and to consider the effects of a war fought in the northern winter. □

* The workshop on the environmental effects of nuclear war was held in Melbourne, 28–29 March 1985, sponsored by the Australian National Committee for the Environment and the New Zealand Committee for the Scientific Committee on Problems in the Environment

Physiological role of Ca^{2+} transport by mitochondria

SIR—We cannot but whole heartedly agree with D J.Miller[1] that the systems which transfer calcium across the inner membrane of mitochondria are of physiological importance. However, we are very surprised that he completely ignores the strong evidence [2-8] which indicates that the major role of these systems is to regulate the concentration of Ca^{2+} within the mitochondrial matrix rather than, as Miller suggests, the concentration of Ca^{2+} in the cytoplasm. When extramitochondrial Ca^{2+} is raised within the physiological range, a parallel increase in intramitochondrial Ca^{2+} will occur and this may activate three important dehydrogenases which occupy key regulatory sites in oxidative metabolism, namely pyruvate dehydrogenase, NAD-isocitrate dehydrogenase and 2-oxoglutarate dehydrogenase. In this way, the formation of reducing power for oxidative phosphorylation can be accelerated under the very conditions where there is likely to be an increased requirement for ATP. Increases in cytoplasmic Ca^{2+} generally stimulate energy-requiring processes such as muscle contraction, secretion or ion-pumping. It is worth emphasizing that these key dehydrogenases have so far only been found to be sensitive to activation by Ca^{2+} in vertebrate tissues[9] and only mitochondria from vertebrate tissues appear to take up Ca^{2+} at an appreciable rate at μMolar concentrations.

The electrostatic charge really is on the surface

SIR — A. A. Berezin recently discussed the question· "What will be a minimum energy configuration of a system of N equal point charges q placed inside a circle?" (see *Nature* **315**, 104; 1985). He considers two configurations, one (A) with all N charges equally spaced around the circumference and the other (B) with one charge at the centre and the remaining $N-1$ equally spaced around the circumference. Assuming a three-dimensional Coulomb potential q^2/r between pairs of charges, he finds numerically that $W(A)<W(B)$ for $N\leqslant 11$ but that for $N\geqslant 12$ (up to at least $N=400$) $W(A)>W(B)$, where W represents the total electrostatic energy of the system. Whilst this answer to the question posed is doubtless true and has some curiosity value, the subsequent suggestion that these results provide an example where charges in a conductor at equilibrium will not reside on its surface is quite wrong.

The fallacy lies in the use of three-dimensional electrostatics for a two-dimensional system. Berezin's circle should properly be regarded as a thin disk and then the charge at the centre of the circle in B is actually at the centre of one of the flat surfaces of the disk. Thus, in the correct three-dimensional interpretation, all of the charges are on the surface of a thin conducting disk for both configurations A and B. (When N is very large, most of the charges will, at equilibrium, reside on the flat surfaces.)

It is of some interest to consider whether any anomalous behaviour arises in the solution of the above problem when it is regarded as strictly two-dimensional. The relevant Coulomb potential is now $-q^2\ln(r/L)$, where L is an arbitary length determining the zero of the potential. It is convenient to choose for L the radius of the circle Then a straightforward analytic calculation shows that $W(B)-W(A)=(q^2/2)[N\ln N-(N-1)\ln(N-1)]>0$ for all $N\geqslant 3$. Thus, in the strictly two-dimensional problem the 'obvious' result is correct and our faith in classical electrostatics is restored.

The complexity and stability of ecosystems

SIR—I read Pimm's[1] article on stability and complexity within ecosystems with great interest. I would not, as an old-fashioned geologist-palaeontologist, pretend that I understood all of the logic involved, nor that I had been able to follow all of the mathematics employed in the May[2] and MacArthur papers to which Pimm refers. There is completely independent evidence from the fossil record supporting Pimm, as well as the earlier work by May[2] to which Pimm refers. Ecologically complex structures such as reef complexes appear historically to have been less stable than level bottom communities If one concludes that the global marine ecosystem has been subjected to stress sufficient to generate large-scale extinction events, such as occurred at the end of the Permian, then it follows that a comparison can by made between the resultant behaviour of the more simple level bottom communities and faunas as contrasted with the trophically far more complex reef community complexes. The nature of the stress(es) is (are) unknown, but it is reasonable to conclude that the trophically different community types reacted differently. Should one or the other, or at least elements of one or the other, survive such a major environmental perturbation it could be concluded that the surviving items were more stable

There are five major intervals during the Phanerozoic when reef community complexes were in existence—including the present (Fig. 3 in ref. 3) In the Lower Cambrian some of the archaeocyathids occur in what many feel are reef community complexes. Such complexes disappear totally at the end of the Lower Cambrian concurrent with an important extinction event, whereas some level bottom taxa, particularly among the trilobites, survive to later radiate in the Middle Cambrian. The second interval of reef community complex is present in the Middle and Upper Ordovician. It disappears totally in the major, terminal Ordovician extinction event, together with much, but by no means all, of the level bottom fauna grouped into many communities. A third reef community complex, with antecedents differing from those of the Middle and Upper Ordovician, appears about one-third of the way through the Upper Silurian and persists until the middle of the Upper Devonian. The major mid-Upper Devonian extinction totally wipes out the reef community complex together with the majority of the level bottom taxa and many of the communities. A fourth reef community complex occurs in the Upper Carboniferous and Permian, derived from totally different antecedents (presumably, as always, level bottom taxa). The terminal Permian extinction event eliminates the Permo–Carboniferous reef community complex, and the bulk of the level bottom taxa and communities. The level bottom survivors ultimately provide the material for a re-radiation which is responsible for the different reef community taxa of the later Triassic.

There are significant taxonomic differences between the Triassic reef taxa and those of the Jurassic–Cretaceous, which suggests that the terminal Triassic extinction event was involved here. At the end of the Cretaceous the tropical–subtropical reef community complex was almost totally wiped out, and it does not reappear in any abundance until the Eocene. The reef community complex then persists until the present, although there are some major changes, such as the addition of the algal ridge complex in the Miocene. Large numbers of coeval

Jurassic–Recent level bottom taxa persist to the present.

In view of the above it is likely that following severe environmental stress capable of generating major extinction events preserved in the fossil record the reef community complex normally is eliminated *in toto*, but that elements, sometimes a large percentage, of the level bottom fauna and its communities persist. Supporting this conclusion is the fact that during the highly provincial Ordovician, Permian, and later Cretaceous, the biogeographically distinctive reef community complexes in different parts of the world terminate at the same time

I suspect that other trophically complex community types such as pelmatozoan thickets, bryozoan thickets and sponge forests, behave in a fashion similar to the reef community complex rather than to the trophically simpler level bottom communities.

It seems clear that the geological-palaeontological evidence strongly supports Pimm[1], May[2], and the others in their conclusions based on a variety of non-geological evidence.

Icosahedra in aluminium / manganese alloy

Sir — The experimental observations of regions of icosahedral order in a splat-cooled alloy of Al/Mn[1,2] have excited considerable comment on a novel type of structure which hitherto had been purely conjectural[3]. One way of considering the proposed structure is as the packing of two kinds of rhombohedral units cells, both having the same cell side but one being acute with $\alpha = 63.43°$ and the other obtuse with $\alpha = 116.57°$ These are repeated according to what has become known as the three-dimensional Penrose pattern, and in a ratio of τ acute units to each obtuse unit, where τ is the golden number 1.618 . . The pattern is intrinsically recursive or hierarchic. I wish to point out further similarities with structures already known. There are at least three types of structures entailing local icosahedral symmetry which may be extended hierarchically for various ranges through the material, according to the balance of the demands of local and of long-range ordering. These include:

(1) Close-packed metal structures where, as pointed out by Frank in 1952[4], 12 spheres will pack icosahedrally around a thirteenth which has 95% of their diameter. This is well known in alloys, most clearly in the structure[5] of $Mg_{32}(Zn,Al)_{49}$ which builds four icosahedral shells before the structure goes periodic Most atoms in it have local icosahedral coordination Probably the driving force behind the structure found by Shechtman *et al* is of this type We might note that "decagonal snowflakes" seem first to have been reported by Adam and Hogan and co-workers[6,7] for the corresponding Al/Fe alloy, but were then not so fully characterized.

(2) The boron compounds, summarized graphically by Sullenger and Kennard[8], where many boron compounds, notably α- and β-boron and $B_{12}C_3$, have rhombohedral unit cells with α about 65 5°, closely corresponding to the acute quasi-unit-cell of the Penrose pattern. Here the symmetry results from the icosahedral clusters of boron atoms produced by the directed bonding requirements of boron to which Berezin[9] has drawn attention. It might be noted that in β-boron the packing is hierarchic, 12 icosahedra being themselves packed icosahedrally around a thirteenth:

(3) Tetrahedrally connected networks, where dodecahedral cages can also appear because of the closeness of the tetrahedral angle of 109.47° to the vertex angles of a pentagon (108°). These occur in clathrasils (cage silicates) and in clathrate hydrates.

Using the structural elements which occur in the zeolite ZSM-39[10] and in the type I gas hydrate[11] we have constructed hypothetical unit cells which would correspond to those required for the Penrose pattern. The acute unit cell is composed of Si–O polyhedra as in the ZSM-39 sheets and these polyhedra are the duals of those in the β-boron structure. The unit cell edges consist of alternating dodecahedra sharing faces (two per edge, so that the cell edge length is 4.45408 times the edge length of the dodecahedron). The corresponding obtuse cell consists of the same faces (arranged with $\alpha = 116.57°$ instead of its supplement) but has, at its centre, a polyhedral cage of 18 faces with two dodecahedral caps (of six pentagons each) and a belt of six hexagons equatorially

Next to this cage the dodecahedra are dislocated and have each two hexagonal and two square faces as well as eight pentagonal faces. Thus, the Penrose pattern reported for alloys might also occur in silicates or hydrates, the dodecahedra of the open tetrahedral structure being dual to the icosahedra of the close-packed metallic structures.

The same two acute and obtuse units may also be assembled in various crystalline ways with, for example, the ratio of 5 acute to 3 obtuse In view of the occurrence of the two kinds of unit cells in the numerical ratio τ in the Penrose pattern, it might be timely to look back at the electron compounds of Hume-Rotheray[12,13], some of which are locally icosahedral, whose electron/atom ratios are 21/13 (these often with an atomic ratio of 8/5 as for Cu_5Zn_8) and 3/2 for CuZn, which might seem to be convergents to the golden number (and also 7/4 which is not), to see where else the Fibonacci series may be detected.

Loess in the Bering Land Bridge

Sir — In his *News and Views* article on the Bering Land Bridge, Colinvaux[1] reported that the *yedoma* deposits of Siberia — long described as alluvium or lacustrine silt — are actually loess, emplaced by wind action when "dry, cold and windswept" conditions prevailed in that part of Siberia. The climatic consequences of this conceptual change are profound and Academician Shilo and co-workers are to be congratulated in bringing about this revolution. Once an idea is in place (for example that a particular deposit is lacustrine silt), it can be very difficult to change; witness the remarkably long time it took to recognize the widespread loess in southern England. But, if the Siberian story is to be fully told there should be a nod of acknowledgement in the direction of Troy Péwé and his proposals that Siberian "silts" were loess[2,3] Péwé and Journaux, admittedly working west of the immediate Bering Strait area, showed that loess was widespread in Yakutia and made a good case for the existence of significant Siberian loess deposits[4].

Refraction scattering as origin of the anomalous radar returns of Jupiter's satellites

T. Hagfors*, T. Gold† & H. M. Ierkic‡

* National Astronomy and Ionosphere Center and
† Center for Radiophysics and Space Research, Space Sciences Building, Cornell University, Ithaca, New York 14853, USA
‡ National Astronomy and Ionosphere Center, Arecibo Observatory, PB 995, Arecibo, Puerto Rico 00613, USA

Three satellites of Jupiter, Callisto, Ganymede and Europa, give anomalous radar returns. We show here that this behaviour would arise as a consequence of 'refraction scattering' rather than the familiar 'reflection scattering' and discuss mechanisms that lead to the predominance of such scattering on these satellites.

THREE of the Galilean satellites of Jupiter, Callisto, Ganymede and Europa, have been shown to have anomalous radar reflection properties in several respects (refs 1-3, D. B. Campbell and S. J. Ostro, in preparation). Although all other planetary bodies that have been investigated by radar, including many different areas on the Earth, give a reflection of a circularly polarized radio wave in which the sense of polarization is reversed, these jovian satellites return a wave that shows predominantly the same sense as the incident one: the shorter the wavelength, the more similar the sense of the waves. If a linearly polarized illumination is used, fully 50% of the energy is returned in the orthogonal polarization, whereas the normal for other bodies is <10%.

Although all other planetary bodies seem to have a total radar cross-section (measuring the sum of returned power in two orthogonal polarizations) of the order of 0.1× the geometrical cross-section, the total cross-section at 12.6-cm wavelength for the galilean satellites are 2.6 for Europa, 1.5 for Ganymede and 0.6 for Callisto[4].

All other planetary bodies give a quasispecular return (glare) from the subearth point, but no such effect occurs for the three galilean satellites in the wavelength region in which they have been studied (3.5-70 cm). In fact, the scattering from these satellites is intermediate between that giving a uniformly bright disk and the slight limb-darkening associated with Lambert scattering[4].

In addition to their remarkable visual appearance[5,6], Callisto, Ganymede and Europa are best characterized as bizarre radar objects. Ostro[4] discusses two possible mechanisms which might explain the peculiar polarization properties. One, which is discarded as unlikely, involves double reflection within hemispherical craters, whereas the other involves multiple internal total reflection on flat boundaries between ice and less dense ice (crushed ice, possibly snow) The polarization results, studied by Monte Carlo calculations, involve boundaries of random and uncorrelated orientations. There is no good explanation of the enormous cross-section in this model

We explore here the alternative possibility that the effect results from what we term 'refraction scattering', a type of scattering which has received little attention and which, has not been encountered previously in radar work with solid materials.

In refraction scattering, one measures a wave that penetrates into the body and whose propagation vector is bent as a result of gentle variations of the refractive index in the medium. In the case of sufficiently large variations of the refractive index, the penetrating wave may be deflected so as to emerge again from the surface. In the geometrical optics limit, the polarization of the wave is retained and we shall show that the unusual polarization properties of the three satellites are then reproduced. For refraction scattering to be dominant one requires: (1) The surface reflection must be small. This requires that the surface material has a low refractive index, n, or that there is a 'matching' transition layer on the surface; (2) the bulk medium has sufficiently low absorption of radio waves to allow long pathways within the medium; (3) the patterns of the variations in n are such as to redirect the propagation vectors by large angles, including 180°; (4) the gradients of n are sufficiently small so that internal reflections will not have a dominant influence.

We describe below internal refractive index structures that satisfy the above four requirements and can reproduce naturally all the bizarre radar properties of the three outer galilean satellites.

Internal refraction

The study of the propagation is based on geometrical optics. A set of equations which describes the rays is:

$$\frac{d\vec{r}}{ds} = \vec{s} \tag{1}$$

$$\frac{d\vec{s}}{ds} = \vec{s} \times \left(\frac{\nabla n}{n} \times \vec{s} \right) \tag{2}$$

where s = arc length along ray and $\vec{s}$ = unit vector along ray. If the medium is horizontally stratified and n is higher in the medium than outside, the angle between the ray direction $\vec{s}$ and the vertical must always be less there than at incidence. Therefore, the ray cannot emerge in the return direction and it is necessary that the surface material is laterally inhomogeneous. Surfaces of constant n might have an appearance as shown in Fig. 1.

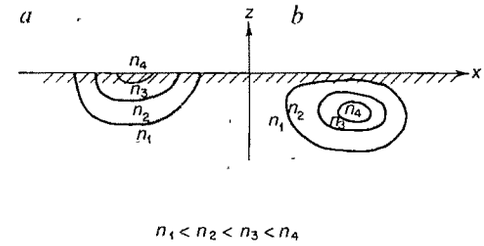

Fig. 1 Contours of constant refractive index: *a*, partly buried; and *b*, fully buried scatter.

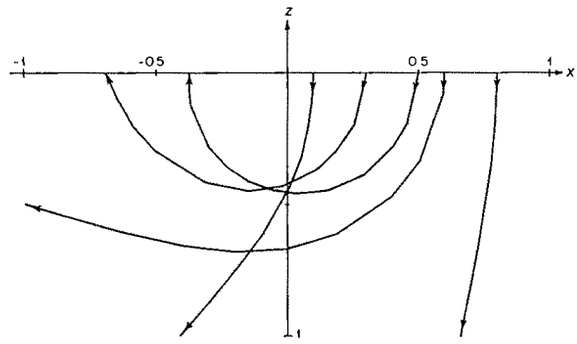

Fig. 2 Rays in gaussian refractivity profiles Normal incidence.

What seems to be required are convex surfaces of constant n surrounding a region of higher n. Further, the curvature of the rays $|\nabla n/n \times \vec{s}|$ must be comparable with the curvature of the equi-refractive index surfaces. These regions of excess refractive index may be quasi-spherical or ellipsoidal, or they may be torus or cylinder shaped with quasi-circular or ellipsoidal cross-sections. Whatever the case may be, such regions, possessing a sufficiently large total range of n, are capable of bending the incoming rays so that they emerge from the surface in all different directions, including the backscatter direction.

We have numerically constructed rays on the basis of equations (1) and (2) for surfaces of several types of n, spherical, ellipsoidal and cylindrical, where n varies either as a cosine, a gaussian or according to the function given below. The refractive index was taken to vary from n_0 at the centre to the value n_1 of the background medium at a distance from the centre, r. Various degrees of submersion of the blobs were considered. The special function mentioned is of the form:

$$n(x,z) = \frac{n_0}{1+(x^2+(z-z_c)^2/a^2} \quad \text{when} \begin{cases} z<0 \\ \sqrt{x^2+(z-z_c)^2} < a\sqrt{n_0/n_1-1} \end{cases} \quad (3)$$

$$= n_1 \quad \text{when} \begin{cases} z<0 \\ \sqrt{x^2+(z-z_c)^2} > a\sqrt{n_0/n_1-1} \end{cases}$$

$$= 1 \quad \text{when} \quad z>0$$

An example of rays traced in a gaussian profile with $z_c = 0$ (Fig. 1*a*), $n_0 = 3.5$, $n_1 = 1$ and $L_x = L_z = 0.4$ (the e-folding distances in the x and the z directions, respectively) is shown in Fig. 2, for normal incidence.

We find no evidence of any qualitative difference between the different models and, therefore, discuss the special case as defined in equation (3) in greater detail, as this is amenable to straightforward analytical treatment. This particular profile, referred to as Maxwell's 'fish eye', has been discussed elsewhere[7].

Consider a spherical blob of excess n of this type fully embedded in a medium of refractive index n_1. We wish to determine the deviation angle between the incoming and existing rays as a function of x (analogous to the impact parameter in collision theory). This relationship can best be derived by reference to Fig. 3. Suppose the radius where the excessive refractive index equals that of the surrounding medium (that is, n_1) is r_1, and suppose the z-axis is aligned with the incoming ray. The ray enters at A. In such refractivity distributions the curvature of the ray is constant and the ray must describe a circle, the centre of which must lie on a line AE normal to the z-axis. A ray going through point A which is a distance r_1 from the centre will cross the diameter through A at a point B on the opposite side of C at a distance $BC = r_2$. In this particular distribution one has.

$$r_1 r_2 = a^2$$
$$a = r_1/\sqrt{n-1} \quad (4)$$
$$n = n_0/n_1$$

The centre of the circular ray is found at the intersection of the bisector of AB with AE, and is thus D. From the construction of Fig. 3 we find that the total deflection angle θ is given by:

$$\theta = 2\arctan\frac{2(n-1)\cdot x\cdot\sqrt{1-x^2}}{n-2x^2(n-1)} \quad (5)$$

where $x \Rightarrow x/r_1$ is the normalized 'impact parameter'.

Figure 4 shows the deflection angle for this particular model plotted against normalized x for various values of n. The actual values of x required to give backscatter (that is, $\theta = 180°$) are given by:

$$x_{180} = \sqrt{\frac{n}{2(n-1)}} \quad (6)$$

and are plotted in Fig. 5*a*. It is clear from this diagram that the rays that are turned back by 180° enter and leave the scatterer near the circumference where n is small. As they will never go through the centre of the scatterer it is not necessary that n actually assumes the value n_0 for backscattering to occur, but it is sufficient that n increases to n_{max}, which it assumes at that point of the ray where it is the closest to the centre of the scatterer. The actual value of this n_{max} can be shown to be:

$$n_{max} = \frac{n}{n-\sqrt{n(n-2)}} \quad (7)$$

Figure 5*b* shows n_{max} as a function of n. It is clear from this diagram that the actual values of $n(r)$ need not in practice reach the peak value at the centre of the scatterer to be able to turn the rays round by 180°.

It can be seen from Fig. 4 that there is a substantial range of x which, for normal incidence, turns the rays back into the hemisphere they came from. If the inner and the outer limits for x are denoted by x_{90} and x_{270}, the fractional energy returned into the hemisphere centred on the incoming wave is $x_{270}^2 - x_{90}^2$. This fraction is plotted as a function of n in Fig. 5*c*.

Finally, we consider the radar backscattering cross-section of one of these spherical enhancements of refractivity. This cross-section is defined as:

$$\frac{\text{Power scattered within } \Delta\Omega}{\text{Incident power density}/4\pi} = \sigma \quad (8)$$

In the geometrical optics approximation discussed above we have found a unique mapping between the area ΔA of the wave front and the solid angle $\Delta\Omega$ onto which this power is scattered. Therefore, the cross-section σ can be expressed as:

$$\frac{S\cdot\Delta A(\Delta\Omega)/\Delta\Omega}{S/4\pi} = 4\pi\cdot\frac{\Delta A}{\Delta\Omega} \quad (9)$$

For an arbitrary direction we have: $\Delta A = x\cdot\Delta x\cdot\Delta\Psi$ and $\Delta\Omega = \Delta\theta\cdot\sin\theta\cdot\Delta\Psi$. Hence we obtain:

$$\sigma = 4\pi\frac{x}{\sin\theta}\cdot\frac{\Delta x}{\Delta\theta} \quad (10)$$

From equation (5) it is easy to show that $\Delta x/\Delta\theta$ remains finite for backscatter, and because x remains near unity σ becomes infinite as $\sin\theta \to 0$. This apparent paradox is resolved if we remember that $\Delta\Omega$ cannot approach zero with ΔA because diffraction eventually starts $\Delta\Omega$ increasing again for small ΔA. We should also note that rays entering and leaving along a circle of radius x will only occur when there is perfect spherical

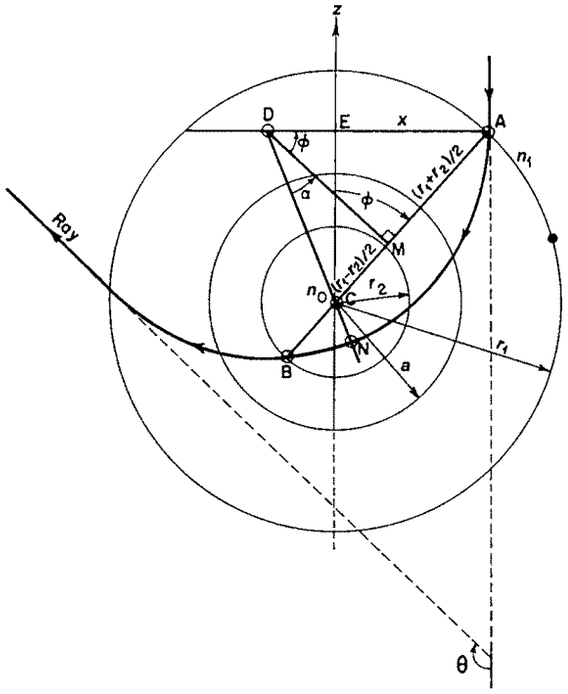

Fig. 3 Derivation of the deflection angle for 'fish eye' distribution of n

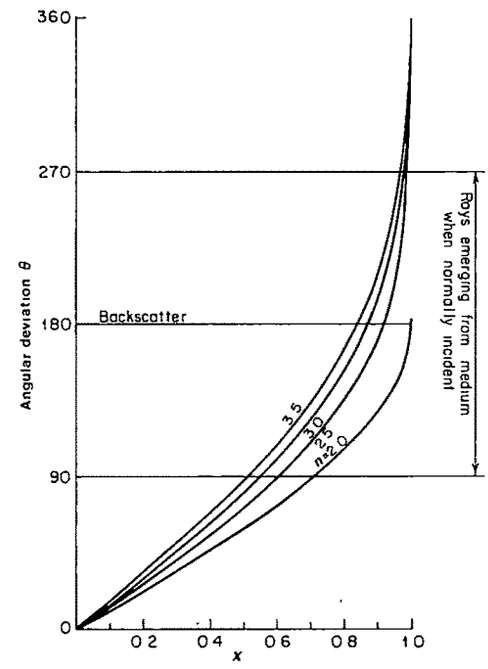

Fig. 4 Angular deviation of rays plotted against 'impact parameter' x with $n = n_0/n_1$ as parameter.

geometry. As soon as we allow for deviations from the perfect spherical symmetry the circular ring will be broken up into disjointed areas and the tendency for backscatter probably decreased. Nevertheless, we suspect that there will also be a distinct preference for backscatter in the real surface

Application to observations

Let us now see how the concept of refraction scattering can be applied to explain the observed radar reflection properties of Callisto, Ganymede and Europa. We must assume that the presence of refractive scatterers is universal on these satellites. The description of the return as a refraction phenomenon, with little reflections from abrupt refractivity changes, implies that a circularly polarized wave will retain its polarization and emerge with the same sense of circular polarization, as required. Our model predicts circular polarization to be maintained fully, in the original sense, whereas the data show this to be only partly so. This may be due to residual surface backscattering, or some internal reflections and/or failure of the geometrical optics approximation to be perfect. Suppose we assume that the backscattering arises as a superposition of two distinct mechanisms, one being the refraction scattering and the other a more usual mechanism, which turns the incoming circular polarization completely into the opposite one in the same manner as an ideal reflecting surface. For a wavelength of 12.6 cm, Ostro[4] quotes for the ratio of 'same circular' (SC) to 'orthogonal circular' (OC) values of 1.5 for Europa and Ganymede and 1.2 for Callisto. It follows that 60% of the power returned from Europa and Ganymede and 55% from Callisto must result from refraction scattering.

The linear polarization results follow from the refraction model as follows: suppose we consider a ray in the xz plane as in Fig. 3. If the linearly polarized E-field is normal to the xz plane, the emerging E-field will be in the same direction as the incoming field. If, however, the E-field is in the incidence plane xz, it will emerge in that plane, but 180° out of phase with a corresponding field normal to xz. This means that a field making

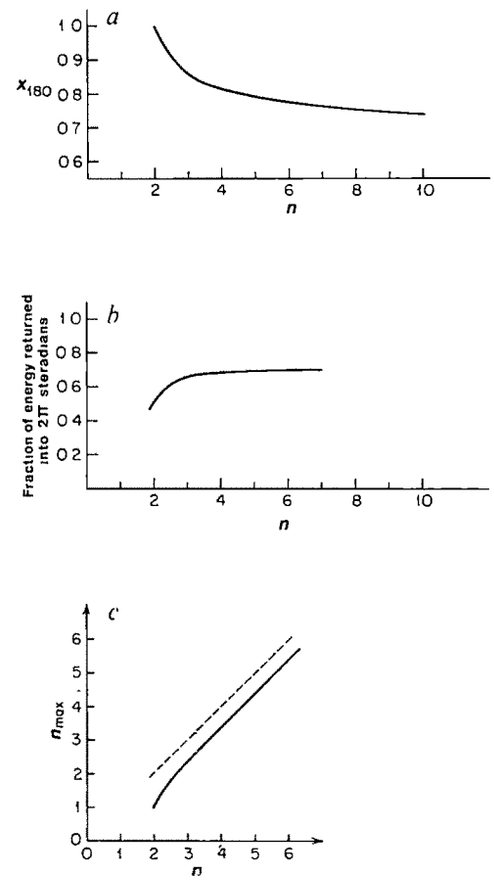

Fig. 5 *a*, Plot of x_{180} against $n = n_0/n_1$ *b*, Plot of maximum refractive index along a backscatter ray against n at the centre *c*, Plot of fraction of normally incident energy emerging from the surface against n.

45° with the xz plane will emerge with its E-field normal to the incoming field. In general, for a field making an angle γ with the plane of incidence, one must have: $E_{SL} = E_0 \cos 2\gamma$ and $E_{OL} = E_0 \sin 2\gamma$ where the indices signify 'same linear' and 'orthogonal linear' as in ref. 4. If powers rather than fields add, and because γ must occur with equal probability between 0 and 360°, one obtains $\sigma_{SL} = \sigma_{OL}$ or $\sigma_{OL}/\sigma_{SL} = 1$. Hence, our ideal model predicts complete depolarization, whereas the data show this ratio to be 0.5. In addition, the assumption of power addition may break down if there is coherency between rays entering and leaving individual blobs, as indeed there is if they are perfectly spherical. Again it seems reasonable to suppose that surface reflections, internal reflections and/or failure of the geometrical optics approximation to decrease the predicted polarization ratio from that of the model. If we imagine that the returned powers be split between refraction scattering and a reflection scattering mechanism as above, and try to reproduce the ratio of orthogonal linear to same linear of 0.47 for Europa and Ganymede and 0.55 for Callisto as observed at 12.6-cm wavelength by Ostro[4], we conclude that 64% of the power returned from the former two can be ascribed to refraction scattering, whereas 70% must be assigned to that mechanism in the case of Callisto. For Europa and Ganymede the consistency is excellent between the deductions made from the linearly and circularly polarized data in view of the limited applicability of our arguments. For Callisto, however, there is an inconsistency between the deductions made, which we suspect results from the failure of the geometrical optics approximation to apply as well as it apparently does on Europa and Ganymede.

We have shown that refractivity inhomogeneities are capable of scattering a substantial fraction of incoming radiation back into space. Such behaviour is consistent with the low emissivity observed by de Pater[8]. The extremely high radar reflectivity is also compatible with the low emissivity and is probably augmented by a preferential backscattering of the individual scatterers, discussed above.

For refraction scattering, or for scattering by internal reflections, the case of normal incidence at the surface has no particular significance; this will account for the lack of a specular reflection highlight near the sub-earth point on these satellites.

Finally, the variation with wavelength referred to earlier receives a natural explanation, in that the geometrical optics approximation will become increasingly poor the larger the wavelength. If this is the explanation of the wavelength dependence, then the size of typical scatterers must be of the order of 1 m.

Discussion

It is noteworthy that the anomalous properties occur just on the only three bodies that have been investigated, which are thought to be composed mainly of ices. Water ice, thought to be the dominant component, is a dielectric of very low dielectric loss, with $n = 1.78$. The other component of the surface material of these bodies is believed to be rock powder whose detailed dielectric properties are not yet known. Lunar rocks and rock powders have been extensively investigated[9] and have values of n ranging from 1.3 for loosely packed material to >3.2 for the dense rock. If there is a tendency for rocks in the domain of the outer planets to be less oxidized, then substantially higher values for the refractivity are to be expected.

Therefore, the physical model we propose is one of a patchwork of rock powders and ices in which n may vary from just over 1 to >3. The uneven distribution of these two components may have resulted from an initial accretion of layers of rock and ice particles, which, together with impacts of larger objects, would have turned a neatly layered system into one that is both laterally and vertically erratic. In particular, it may be that the overturning of material in an impact could create the torus-shaped structures referred to above. Also, impact on a loosely packed but cohesive matrix of rock powder left behind by evaporation of volatiles could be compacted and form the semi-spherical volumes of excess n discussed above. Evaporation of volatiles from the surface may have helped to concentrate rock powders. Outpouring of liquid water from deeper and warmer regions may have laid down 'clean' ice. Both these processes would contribute to the creation of a heterogeneous medium.

The requirement of low dielectric loss may well be satisfied because of the very low temperatures. Ice well below its melting point leads to absorption lengths of thousands of wavelengths. The lunar rocks gave results for the absorption length between 100 and 300 wavelengths. At the low temperatures of these icy satellites it is likely that the low dielectric loss of these rock powders would be maintained despite the presence of water in solid form. (At the higher temperatures prevailing on earth, hydrated rocks dominate and exhibit a high dielectric loss.)

The condition of low surface reflectivity may be met by having a very tenuous medium (therefore of low n) in which the regions of excessive refractivity are embedded. If the medium is not so tenuous, it may be that a low density transition layer, as found on the Moon, can provide the proper match and serve to suppress the reflection at the surface. An extremely fluffy outer surface of rock powder or snow may have resulted from the partial evaporation of ices from the pore spaces in the material. In addition it may be that the interesting mechanism suggested by Spencer and Maloney[10], which explains the migration of water on Callisto as sublimation and capture in cold traps, may have played a role in creating the heterogeneous conditions required. This mechanism alone would apparently create depletions in refractivity rather than enhancements, and, therefore, must have been modified by some other mechanism, such as impact cratering, to create the favourable conditions for refraction scatter to occur.

Also within the material, sharp discontinuities of n must be sufficiently rare for refraction to remain the dominant cause of backscatter. If rock powder and ices make up the bulk of the material, this implies that although variations of the mixing ratio of these two substances are responsible for the refraction, they are generally not too abrupt on the scale of the radio wavelengths used.

Conclusions

We have shown that refraction scattering from convex regions of excess n has all the properties required to explain the observed radar returns from Callisto, Ganymede and Europa. We conjecture that the conditions which prevail on these satellites are probably ideal for the creation of the refractivity structure required to make refraction scattering important. Therefore, we conclude that refraction scattering is the most likely explanation for the bizarre scattering properties of these satellites.

We thank Gordon Pettengill and Steve Ostro for helpful discussions. The National Astronomy and Ionosphere Center is operated by Cornell University under contract with the NSF.

Cloning, sequence and expression of two distinct human interleukin-1 complementary DNAs

Carl J. March*, Bruce Mosley†, Alf Larsen†, Douglas Pat Cerretti†, Gary Braedt†, Virginia Price†, Steven Gillis, Christopher S. Henney, Shirley R. Kronheim*, Kenneth Grabstein‡, Paul J. Conlon‡, Thomas P. Hopp* & David Cosman†

Departments of * Protein Chemistry, † Molecular Biology and ‡ Cellular Immunology, Immunex Corporation, 51 University Street, Seattle, Washington 98101, USA

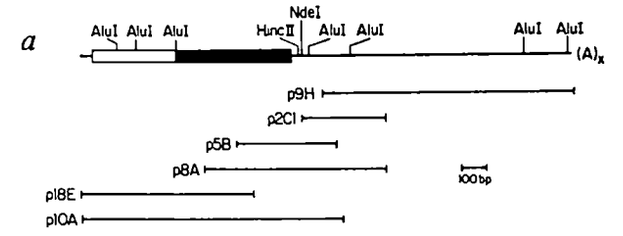
Two distinct but distantly related complementary DNAs encoding proteins sharing human interleukin-1 (IL-1) activity (termed IL-1α and IL-1β), were isolated from a macrophage cDNA library. The primary translation products of the genes are 271 and 269 amino acids long, although expression in Escherichia coli *of the carboxy-terminal 159 and 153 amino acids produces IL-1 biological activity.*

INTERLEUKIN-1, a protein produced by activated macrophages, mediates a wide range of biological activities, including stimulation of thymocyte proliferation via induction of interleukin-2 (IL-2) release, stimulation of B-lymphocyte maturation and proliferation, fibroblast growth factor activity and induction of acute-phase protein synthesis by hepactocytes[1]. IL-1 has also been reported to stimulate prostaglandin and collagenase release from synovial cells, and to be identical to endogenous pyrogen[1].

The question of whether this array of activities resides in a single protein has excited much discussion. The conventional approach to its resolution has been to purify IL-1 activities from the culture supernatants of macrophages activated with lipopolysaccharide (LPS), but the results have been ambiguous. Apparently homogenous protein preparations display characteristic IL-1 activities, including IL-2 induction and pyrogenicity. However, many reports associate IL-1 with proteins of relative molecular mass (M_r) ~15,000 and 30,000 and isoelectric points ~*p*H 5 and 7 (refs 1-8). These studies suggest that either a considerable amount of protein processing leads to the appearance of active polypeptides of differing sizes from a single protein, or that activities characteristic of IL-1 are shared by several different proteins.

To clarify these issues, we attempted to clone the gene(s) responsible for IL-1 activity using two different strategies. First, we screened macrophage complementary DNA clones by hybridization to macrophage RNA, followed by *in vitro* translation of the selected RNA and detection of IL-1 biological activity using a sensitive assay that measures its capacity to induce IL-2 synthesis by a cloned T-cell line[9]. Second, we purified to homogeneity a protein having IL-1 activity[2], performed partial amino-acid sequence analysis, constructed an oligonucleotide probe based on this sequence and used the probe to screen a macrophage cDNA library.

These experiments led to the isolation of two distinct cDNAs encoding proteins with a characteristic IL-1 activity, defined by the induction of IL-2 synthesis by a T-cell line or by thymocytes. These proteins, which we term IL-1α and IL-1β, showed only distant homology to each other. Both molecules seem to be synthesized as larger precursors that are processed to smaller forms. Here we discuss the relationship of these findings to recent reports of other IL-1 cDNAs[10,11].



Isolation of IL-1 messenger RNA

Optimal conditions for the production of IL-1 messenger RNA from peripheral blood monocytes were established. Initially, mRNA was injected into *Xenopus* oocytes and the supernatants assayed for biological activity. Low levels of IL-1 could be detected using an assay that measures the capacity of IL-1 to stimulate IL-2 release from a phytohaemagglutin-stimulated cloned murine lymphoma cell line (LBRM-33-1A5) (termed the 1A5 conversion assay)[9]. This assay is ~1,000-fold more sensitive than the standard IL-1 assays of direct thymocyte mitogenesis or co-mitogenesis[2], and was used as the basis for the molecular cloning of IL-1. Stimulation of the monocytes with 10 μg ml^{-1} *Escherichia coli* lipopolysaccharide (LPS) for 12 h gave the highest levels of IL-1 mRNA. Unstimulated monocytes contained little IL-1 mRNA.

Single bacterial colonies were picked into LB-broth plus 15 μg ml^{-1} tetracycline and grown overnight, then 48 1-ml cultures were combined and plasmid DNA isolated according to standard procedures[27] with the modification that the plasmid DNA was ribonuclease treated and separated from small-M_r nucleic acids by chromatography on a Sephacryl S-400 column. 10 μg plasmid DNA was digested with *Bam*HI, denatured and bound to nitrocelluose filters (Schleicher and Schuell)[28]. Each filter was hybridized to 20 μg of LPS-stimulated macrophage RNA overnight at 50 °C in 50% formamide, 100 mM PIPES *p*H 6.8, 0.4 M NaCl, 10 mM EDTA, then washed 10 times at 65 °C in 1×SSC, 0.2% SDS and five times in 0.2×SSC at 65 °C. The bound RNA was eluted in boiling water containing 6.6 μg μl^{-1} yeast transfer RNA and recovered by ethanol precipitation, then translated in rabbit reticulocyte lysates[29,30] and an aliquot of the lysate was assayed for IL-1 activity in the 1A5 conversion assay[9]. ND, not detected. No biological activity over the background control was observed at a sample dilution of 1:50. Control, 10 μg pBR322 DNA was bound to the filter as a negative control

b

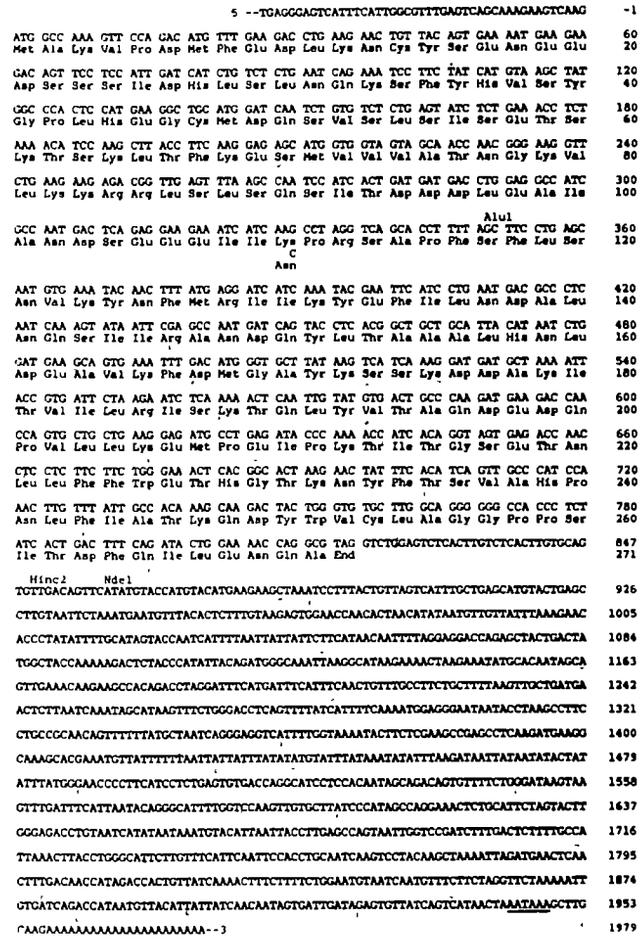

Fig. 1 *a*, Restriction endonuclease map of human IL-1α Coding sequences are boxed. Shaded boxed region represents the presumptive mature form of IL-1α Below are shown the cDNA clones used for sequencing. One clone, p10A, contains the entire coding region Each cDNA clone begins and ends with *Pst*I sites, generated by the cloning procedures. *b*, Nucleotide sequence and predicted amino-acid sequence of IL-1α. Nucleotides and amino acids are numbered from the presumed initiator codon The star under Ser 113 indicates the position of the presumed mature NH_2 terminal. The nucleotide sequence differs between p18E and p10A at base 330 (G→C) which would cause an amino-acid change, Lys 110→Asn The 3′ maturation signal[36] is underlined Coordinates of cDNA clones shown in *a* are: p18E, nucleotides −45–652, p10A, −35–1,075; p8A, 447–1,195; p5B, 591–995; p2C1, 860–1,194; p9H, 928–1,979.

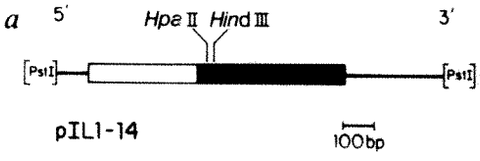

Methods. *a*, Size fractionation of LPS-stimulated macrophage RNA Human peripheral blood mononuclear cells were isolated as described previously[2]. Macrophages were purified further by adherence to plastic tissue culture flasks and stimulated with 10 μg ml^{-1} LPS for 12 h. Total RNA was isolated by a modification of the guanidinium thiocyanate and guanidine hydrochloride methods[12,31]. Cells were solubilized in 4 5 M guanidinium thiocyanate containing 50 mM sodium citrate, *p*H 7 0, 5% β-mercaptoethanol and 0 5% sodium sarcosinate Following sonication, 0 6 vol ethanol was added and RNA precipitated at −20 °C overnight. The pelleted RNA was resuspended in 8 M guanidine hydrochloride containing 50 mM sodium acetate, *p*H 6.0, extracted with phenol/chloroform/isoamyl alcohol (25:24·1) and reprecipitated with 0.6 vol ethanol, as above Following a wash with 80% ethanol, the RNA pellet was dissolved in water and chromatographed on an oligo(dT) cellulose column to select polyadenylated RNA[32]. Polyadenylated RNA (250 μg) was then fractionated on 1.5% ultra-low-melt agarose gels (Marine Colloids) containing 10 mM methyl mercuric hydroxide[12]. Gel slices were melted at 65 °C in binding buffer (0.5 M NaCl, 10 mM Tris-acetate *p*H 7.5, 1 mM EDTA) and applied to small columns of NACS-52 resin (BRL) The columns were washed with binding buffer, RNA eluted with 6 M guanidine hydrochloride, 10 mM Tris-acetate *p*H 7.5, 1 mM EDTA, mixed with 10 μg yeast tRNA and purified by several ethanol precipitations and washes to remove the guanidine hydrochloride. RNA was then redissolved in 15 μl water for injection into *Xenopus* oocytes. For each fraction, 40 stage VI oocytes were each injected with 50 nl RNA and incubated overnight at 19 °C in Barth's medium. Undamaged oocytes were transferred to 300 μl of 1 2 complete Click's medium containing 1.5 mM $CaCl_2$ and 100 μg ml^{-1} gentamycin and incubated for 2 days at 19 °C. Supernatants were assayed for IL-1 activity using the 1A5 conversion assay[9] (see text) Double-stranded cDNA was synthesized from the size-fractionated RNA using standard techniques[12,13]. The cDNA was size-fractionated on a Sephacryl S-400 column and fractions >500 bp long were pooled and tailed with dCMP residues[33] The tailed cDNA was annealed to dGMP-tailed, *Pst*I-cut pBR322 (NEN) and used to transform *E. coli* strain MM294 according to the procedure of Hanahan[34], ~20,000 transformants were obtained from 25 ng cDNA. 5,000 transformants were picked into microtitre plates and grown to saturation in LB-broth containing 15 μg ml^{-1} tetracycline. The 5,000 selected transformants were replica-plated onto nitrocellulose filters and hybridized to ^{32}P-labelled cDNA synthesized from polyadenylated, unstimulated macrophage RNA[12]. Colonies hybridizing strongly were eliminated from further consideration and 768 of the remaining colonies screened by the hybrid selection procedure described in Table 1, resulting in the isolation of p2Cl. The insert from p2Cl was ^{32}P-labelled by nick-translation and used to screen the whole library, resulting in the identification of p9H. An oligonucleotide was synthesized from the sequence of p2Cl, 5′GTTGGTTCCACTCTTAC3′, complementary to nucleotides 959–975 (*b*). This was ^{32}P-labelled by T_4 polynucleotide kinase and [γ-^{32}P]ATP and used to rescreen the library[35], resulting in the isolation of clones p5B and p8A A 324-bp *Pst*I/*Hae*III fragment isolated from p8A was then used to probe the library, resulting in the isolation of p18E and p10A. *b*, Restriction endonuclease fragments from the cDNA clones were subcloned into M13mp18 or mp19 (ref 37) and sequenced by the chain-termination method[38] as described previously[39,40]

The low levels of IL-1 activity secreted by the oocytes raised the possibility that IL-1 might be sequestered inside the oocyte. However, oocyte homogenates were highly inhibitory to the 1A5 conversion assay because, when 4,000 U of purified IL-1 was mixed with homogenates from uninjected oocytes, no IL-1 activity could be demonstrated. Subsequently, we found that mRNA translated in rabbit reticulocyte lysates could generate much higher levels of IL-1 activity, so we used this system.

Polyadenylated RNA showing IL-1 activity was size-fractionated on denaturing agarose gels and fractions assayed for IL-1 mRNA content (data not shown). The fraction having the highest activity was used to construct a cDNA library of ~20,000 transformants in plasmid pBR322 by established techniques[12,13].

IL-1α-containing plasmids

The production of high levels of IL-1 activity in reticulocyte lysates allowed the identification of IL-1 cDNA clones by hybrid selection of biologically active IL-1 mRNA. Starting with 5,000 transformants from the library, we eliminated from consideration those clones that were resistant to ampicillin (which presumably lacked a cDNA insert) and those that contained cDNAs corresponding to abundant mRNA common to both unstimulated and LPS-stimulated macrophages. Such clones were identified by their strong hybridization to ^{32}P-cDNA synthesized from unstimulated macrophage RNA. Of the remaining 2,000 clones, 768 were screened in pools of 48 for IL-1 activity using a hybrid selection procedure (Table 1). Two pools of plasmid DNA were positive in this assay and were broken down further until two individual cDNA clones (p2C1 and p11F6) were obtained that selected RNA yiedling IL-1 biological activity. Although the IL-1 activity selected by p2C1 in the third screen was not as great as that selected by p11F6, it was significantly above background values. In subsequent experiments, the two plasmids selected comparable levels of IL-1 activity (several thousand U ml^{-1}), and were found to cross-hybridize (data not shown).

Fig. 2 *a*, Restriction map of pIL-1-14. *Pst*I sites in brackets are those generated by the cloning procedure. Box, protein coding sequence; open box, N-terminal portion of the primary translation product removed during proteolytic processing; closed box, M_r 17,500 biologically active portion of IL-1β isolated from activated macrophage supernatants. *b*, Nucleotide and predicted amino-acid sequence of the IL-1β primary translation product. Amino acids in capitals indicate those residues confirmed by protein sequencing analysis. Numbering of nucleotides is negative for the 5′ non-coding region and positive from the presumed initiator methionine codon. Protein numbering begins at the initiator methionine. Underlined amino acids refer to the first cycle of different protein sequence analyses. Star, NH_2-terminal residue of the M_r 17,500 form of IL-1β (Ala 117). The *Hpa*II site was used in construction of plasmids used for expression of IL-1β (Fig 4, Table 2).

Methods. *a*, A cDNA library was constructed from size fractionated, polyadenylated human macrophage RNA as described in Fig. 1*a*. A 62-nucleotide probe was constructed using the amino-acid sequence data corresponding to amino acids 133–158 (see below). The probe (5′ ACTTGTTGTTCCATGTCTTGGCCTTGCAGG TGCAGGGCTTTCAGTTCGTAGGGGCCGGACAT 3′) was labelled to high specific activity with T_4 polynucleotide kinase and [γ-^{32}P]ATP and used to screen the library[35]. Positive colonies were analysed by restriction mapping using standard techniques[12]. *b*, Nucleic acid sequencing: Various restriction fragments of pIL-1-14 were cloned into M13mp18 or M13mp19 and sequenced as described in Fig. 1. Protein sequencing: amino-terminal sequencing: ~12 μg (680 pmol) unmodified IL-1β was placed in a protein sequencer (Applied Biosystems Model 470A) and analysed according to manufacturer's specifications. Phenylthiohydantoin amino acids were identified by HPLC as described previously[41]. Residues 117–123 and 125–136 were identified and tryptic peptides prepared as follows: 10.5 μg (600 pmol) IL-1β was partially digested with 250 ng trypsin for 2 h at 25 °C, reduced, carboxymethylated and injected onto a Vydac C18 Model 218TP54 4.6 × 250 mm HPLC column and fractionated by a 0.5% min^{-1} linear gradient of acetonitrile in 0.1% (v/v) trifluoroacetic acid at 0.7 ml min^{-1}. Fractions (0.7 ml) were concentrated and analysed by sequencing. Residues identified were 121–123 and 125–126; 133–158, 162–167 and 169–171. *S. aureus* V8 protease-specific peptides were obtained as follows: 10.5 μg (600 pmol) IL-1β was digested with 250 ng V8 protease for 8 h at 25 °C, reduced, carboxymethylated and fractionated as described above. Residues identified were 181–186, 200–203, 213–218 and 230–238. Fragmentation by CNBr was performed on the same sample that had been used to obtain the N-terminal sequence. After 20 cycles of NH_2-terminal sequencing, the filter in the glass block holder was removed and placed into a small beaker. The filter was saturated with 30 μl of a solution containing 15 mg CNBr in 100 μl 70% (v/v) HCOOH. The remaining solution was placed open in the beaker, the beaker sealed with Parafilm and placed in the dark. After 20 h at room temperature, the filter was dried under vacuum and placed back into the sequencer. Five simultaneous sequences were seen, differentiated from each other by their wide range of relative yields. We identified clearly residues 153–158; 161–167 and 169–171; 212–218, 220–224 and 225–226; 247–252; and 265–269. All these amino acids confirmed the sequence obtained from the cDNA.

Nucleotide sequence analysis of p2C1 showed that it contained a non-coding region of IL-1 mRNA. Therefore, nick-translated and oligonucleotide probes derived from p2C1 were used to isolate further homologous cDNA clones from the library (Fig. 1). 5′ probes from these new clones were then used to identify further cDNA clones, each able to select biologically active IL-1 mRNA (data not shown). The nucleotide sequence of IL-1 mRNA defined by the overlapping cDNA clones is shown in Fig. 1. It predicts an mRNA size of at least 2,002 nucleotides, excluding the poly(A) tail. Primer extension analysis indicated that the IL-1 mRNA extends ~15 nucleotides upstream of the sequence shown here (data not shown). A single, large open reading frame of 271 amino acids was found at the 5′ end of the mRNA encoding a protein of predicted M_r 30,606 (designated IL-1α). Although IL-1 is thought to be a secreted protein, the predicted sequence does not contain a classical N-terminal signal sequence of largely hydrophobic amino acids such as are found in other lymphokines[14–17], nor does it have any long internal hydrophobic amino-acid sequences.

While this work was in progress, Lomedico *et al.* published the cloning and sequencing of a murine IL-1 cDNA[10]. Comparison of the two predicted amino-acid sequences reveals that they are 62% homologous, suggesting that the gene cloned here is the human homologue. They have also defined the N-terminus of a subset of biologically active murine IL-1 molecules at Ser 115 (ref. 10). By matching the sequences of murine IL-1 and human IL-1α, this corresponds to Ser 113 in the human sequence. The relationship between different IL-1 molecules will be discussed below.

Cloning of IL-1β

In a separate approach to the definition of IL-1, we have reported previously the purification (from activated macrophage supernatants) of a M_r 17,500 protein with IL-1 activity[2]. We attempted to sequence this molecule to design oligonucleotide probes to identify IL-1 cDNA clones. However, amino-terminal sequence analysis of this purified protein yielded ambiguous results because of a low absolute yield in the first cycle, followed by a very sharp decline in repetitive yield. Therefore, we fragmented the molcule enzymatically. We performed a partial tryptic digest on 600 pmol protein and, after reduction and carboxymethylation, fractionated the resulting peptides by reversed-phase HPLC. A M_r 13,500 peptide was isolated in high yield. Sequence analysis of this fragment showed a continuous stretch of 26 amino acids followed by 10 identifiable residues in the subsequent 14 cycles. The 26 amino-acid stretch (Ser 133–Phe 158; Fig. 2) was used to design (based on published human codon frequencies) a synthetic, 62-base oligonucleotide probe (see Fig. 2 legend) which was ^{32}P-labelled and used to screen the size-fractionated macrophage cDNA library. Several positively

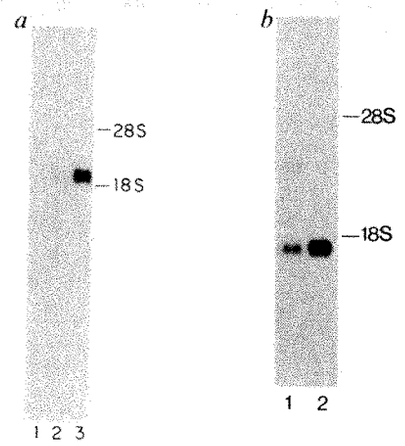

Fig. 3 Northern blot analysis of: *a*, IL-1α; *b*, IL-1β mRNA. *a*, Lane 1, 5 μg total RNA from mitogen-stimulated peripheral blood T cells; lane 2, unstimulated peripheral blood macrophages; lane 3, LPS-stimulated peripheral blood macrophages. *b*, Lane 1, 5 μg total RNA from unstimulated peripheral blood macrophages; lane 2, LPS-stimulated peripheral blood macrophages.

Methods. Total RNA was extracted from LPS-stimulated and unstimulated macrophages as in Fig. 1, and from peripheral blood T cells stimulated with the mitogens concanavalin A (20 μg ml^{-1}) and phorbol myristic acetate (10 ng ml^{-1}) as described previously[35]. RNA was electrophoresed on 1.5% agarose gels containing formaldehyde and transferred to nitrocellulose filters[12]. Blots were hybridized with ^{32}P-RNA probes synthesized by SP6 polymerase as described previously[42]. The IL-1α probe used was derived by subcloning a 1,020-bp *Pst*I/*Hin*dIII fragment from p9H into pSP64 (Promega Biotec). The IL-1β probe was derived by subcloning the insert from pIL-1-14 into the *Pst*I site of pSP64. Hybridization was for 16 h at 63 °C in Stark's buffer[43]. Blots were washed in 0.1 × SSC for 30 min at 68 °C and autoradiographed with intesifying screens. The position of large (28S) and small (18S) ribosomal RNAs indicated were determined by direct visualization of the unbaked blot with a short-wave ultraviolet lamp.

hybridizing clones were isolated, one of which, pIL-1-14, was chosen for nucleotide sequencing (Fig. 2). The clone, 1,124 base pairs (bp) long, contained the probe sequence with 12 mismatches out of 62 nucleotides and encoded the protein sequence obtained from the M_r 13,500 tryptic fragment.

The sequence of pIL-1-14 defined a single large open reading frame of 269 amino acids encoding a protein with a predicted M_r of 30,749 (Fig. 2). We found a presumptive initiator methionine codon flanked by sequences closely conforming to the consensus sequence suggested for mammalian translational initiation[18] 78 bp from the 5′ end of the pIL-1-14 cDNA sequence. The cDNA insert contained 240 nucleotides of 3′ non-coding sequence but did not extend far enough to include the polyadenylation site and poly(A) tail. Primer extension analysis indicated that the message extended ~10 nucleotides 5′ of pIL-1-14 (data not shown). The predicted amino-acid sequence of the protein encoded by pIL-1-14 (designated IL-1β) showed only limited homology to that of IL-1α (see below).

To establish the location of the M_r 17,500 form of IL-1 in the 269 amino-acid open reading frame, we sequenced a larger preparation (~680 pmol) of purified IL-1β, and could distinguish a major signal corresponding to the sequence starting at Ala 117, and which agreed with the sequence predicted from pIL-1-14 for the subsequent 20 amino acids (Fig. 2). Although a yield of only 266 pmol (39%) was obtained for the N-terminal sequencing run, no other discrete N-termini were found. These results were confirmed by additional runs on the same, and other, preparations of IL-1 protein. A similar result was reported for murine IL-1 (ref. 10). Sequence analysis of peptides generated from a *Staphylococcus aureus* V8 protease digest and from *in situ* cyanogen bromide cleavage of IL-1β (Fig. 2 legend) yielded additional confirmation of protein sequence predicted by the cDNA sequence at 96 positions of the 153 amino-acid sequence (capitalized amino acids in Fig. 2) predicted for the M_r 17,500 IL-1β, including definition of the carboxy-terminus at Ser 269. A potential *N*-glycosylation site is present at Asn 123, although there is no previous evidence that IL-1β is a glycoprotein[2]. Direct protein sequencing detected asparagine at this position, confirming the absence of carbohydrate. Thus, the M_r 17,500 form of IL-1β extends from Ala 117 to Ser 269 and represents a carboxy-terminal segment of the primary translation product. The predicted M_r of this form of IL-1β is 17,377, in close agreement with the M_r of 17,500 determined previously[2].

Similar to IL-1α, the amino-acid sequence predicted for the primary translation product of IL-1β does not contain any N-terminal or internal stretches of hydrophobic amino acids that resemble conventional secretory signal sequences.

IL-1 mRNA expression

We analysed IL-1 mRNA levels in stimulated and unstimulated macrophages by Northern blotting using IL-1α and IL-1β-specific probes (Fig. 3). In both cases, we detected a single predominant species of RNA much more abundant in LPS-stimulated than unstimulated macrophage RNA. The low levels of IL-1 RNA in unstimulated macrophages resulted from partial activation during culture as cells cultured under pyrogen-free conditions do not have detectable IL-1 RNA (K.G. and A.L., unpublished). The sizes were estimated to be 2,100–2,200 nucleotides for IL-1α mRNA and ~1,800 for IL-1β. Neither IL-1α mRNA (Fig. 3*a*) nor IL-1β mRNA (data not shown) was detectable in RNA extracted from peripheral blood T cells activated with the mitogens concanavalin A and phorbol myristic acetate, even on longer exposure of the autoradiogram.

Interestingly, IL-1β mRNA seemed to be ~10-fold more abundant than IL-1α mRNA. IL-1α cDNA clones were present at a frequency of ~1 in 1,000 in the size-fractionated cDNA library, whereas IL-1β cDNA clones were present at ~1 in 100. Given an estimated enrichment for IL-1 mRNA by agarose gel electrophoresis of ~10-fold, this would predict abundances of ~0.01% and 0.1% of the poly(A)$^+$ RNA from LPA-stimulated macrophages for IL-1α and IL-1β mRNAs, respectively.

Although IL-1α and IL-1β mRNAs are induced by the same stimulus (LPS), it is not known whether they are produced by the same cell type in the peripheral blood monocyte population. The availability of specific nucleic acid and antibody probes for IL-1α and IL-1β should clarify this issue.

Expression of IL-1α and IL-1β activity

Evidence presented here for IL-1β, and by Lomedico *et al.* for the murine homologue of IL-1α[10], suggests that the biological activity of the two IL-1 molecules resides in their C-terminal 153 and 159 amino acids, respectively. To prove this, we constructed plasmids designed to direct synthesis by *E. coli* of these portions of IL-1α and IL-1β. We used synthetic oligonucleotides that added a ribosome binding site and initiation codon to the C-terminal 159 amino acids of IL-1α (beginning at Ser 113) or to the C-terminal 153 amino acids of IL-1β (beginning at

Table 2 Expression of IL-1 biological activity

Plasmid	IL-1 in culture (U ml^{-1})	
	30 °C	43 °C
pILPα	3.2×10^3	5.1×10^6
pILPβ	4.1×10^2	1.4×10^6
pILPc	ND	ND

Cells were grown at 30 °C to an $A_{720} = 1.0$ in induction broth (M9 medium supplemented with 32 g l^{-1} tryptone, 20 g l^{-1} yeast extract and 0.4% glucose). Cultures were then grown at 43 °C for 1 h. Cells from 1 ml culture were pelleted and quick-frozen on dry ice/methanol. Before assay the cells were dissolved in 50 μl 7 M guanidine hydrochloride. IL-1 biological activity was assayed as described for Fig. 1*a*. Results are expressed as IL-1 units per ml *E. coli* culture. ND, not detected. No biological activity over background control at a sample dilution of 1 : 50 (1A5 assay).

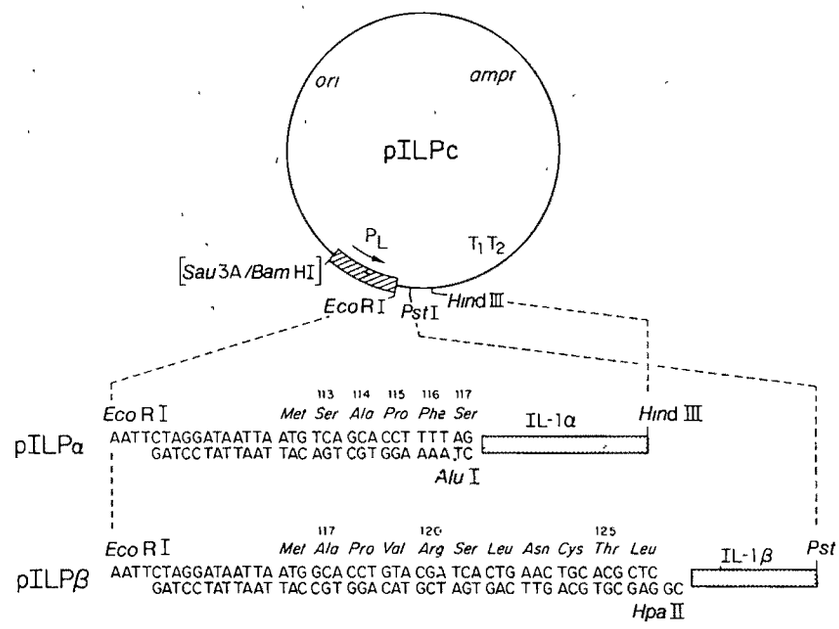

Fig. 4 The expression plasmid, pILPc, was constructed by replacing the *Bam*HI/*Eco*RI fragment of pKK223-3 (Pharmacia), containing the Tac promoter, with a *Sau*3A/*Eco*RI fragment from pPLc28 (ref. 44) that contains the λ P_L promoter. Synthetic oligonucleotides were used to provide an *E. coli* ribosome binding site, a translational initiation codon and the codons for amino acids Ser 113–Ser 117 for IL-1α or Ala 117–Leu 126 for IL-1β. To construct pILPα, the oligonucleotides were ligated together with a 720-bp pair *Alu*I/*Hin*dIII fragment into *Eco*RI/*Hin*dIII-cut pILPc. This fragment was derived from the yeast expression plasmid, pYαfIL-1α (V.P., unpublished), and specifies amino acids 118–271 of IL-1α followed by 200 bp of sequence originally derived from the 3′ non-coding region of the human *IL-2* gene. To construct pILPβ, the oligonucleotides were ligated together with a 669-bp *Hpa*II/*Pst*I fragment from pIL-1-14 into *Eco*RI/*Pst*I-cut pILPc. This fragment specifies amino acids 127–269 of IL-1β. T_1T_2, transcriptional termination sites from the rrnβ operon pILPc, pILPα and pILPβ transformed into *E. coli* strain ΔHI (ref. 45) that produces a thermolabile repressor of the P_L promoter.

Ala 117), and placed this under transcriptional control of the λ phage P_L promoter (Fig. 4). The resulting plasmids, pILPα and pILPβ, were introduced into cells containing a thermolabile repressor of P_L transcription. On heat induction, the cells produced high levels of IL-1 activity that could be extracted from the cells by 7 M guanidine hydrochloride as detected in the 1A5 conversion assay (Fig. 4, Table 2) or thymocyte co-mitogenesis assay[2] (data not shown). No IL-1 activity was found in cells transformed with a control plasmid lacking IL-1 sequences.

Interleukin-1 relationships

To determine the degree of homology between the IL-1β sequence and the related sequences for human IL-1α and murine IL-1[10], we aligned them as shown in Fig. 5*a*, with several insertion/deletion gaps to obtain the maximum number of identical residues. The amino-acid sequences for human IL-1α and murine IL-1 are closely related, having 167 out of 271 (62%) identical positions, whereas IL-1β is only distantly related to either of the other molecules, with 70 out of 271 identical positions (26%) with human IL-1α and 80 out of 270 (30%) with murine IL-1. Slightly over half of the identical positions between the IL-1 proteins occur in the M_r 17,500, C-terminal biologically active portion of the molecules, and a large proportion of these occur in the middle and C-terminal regions (Val 164–Ile 266 of IL-1α) of the M_r 17,500 forms, suggesting that these areas comprise portions of the molecules more critical for their biological activities. In contrast, very few residues are shared between the three proteins in the N-terminal third (Ser 113–Ala 163 of IL-1α) of the processed IL-1 sequences. This sequence diversity suggests that the N-terminal region of the M_r 17,500 form either is not involved in a biological role or provides an area for expression of different biological functions in each molecule.

Of the residues common to all three proteins, 47% (28 of 59) occur in the portion of the primary translation product that precedes the active M_r 17,500 IL-1 segment. In this region, 81 out of the 167 identical residues between human IL-1α and murine IL-1 occur, showing that these portions of the molecules are more homologous (81 of 112; 72%) than the M_r 17,500 IL-1 segments (86 of 159; 54%). IL-1β also has more homology with both molecules in this region. Such a degree of homology would not be expected for a non-functional portion of a protein. Therefore, it seems plausible that the N-terminal halves of the IL-1 gene products serve some as yet unknown biological function. Indeed, several biological activities have been associated with high M_r forms of IL-1[8,19], some of which may be related to the conserved N-terminal segment.

Note that although there is only 26% homology between the two human IL-1 protein sequences, significantly more occurs at the nucleic acid level (45%). Thus, it is possible that a gene duplication event gave rise to the two IL-1 molecules. The degree of divergence between the two sequences indicates that the duplication was an early event on the evolutionary scale[20].

The structural features common to all three IL-1 polypeptides are illustrated in schematic form in Fig. 5*b*. All three primary translation products have a higher degree of homology in the amino-terminal 75–80 residues. This segment (N in Fig. 5*b*) does not seem to contain a signal sequence or membrane spanning region. In fact, it has no features that would serve to distinguish it from typical globular protein sequences. Following the N-terminal domain, all three IL-1 molecules have a short section of multiple basic residues (+ in Fig. 5*b*). This segment is reminiscent of known proteolytic processing sites in prohormone precursors[21,22], maturation cleavage sites of the haemagglutinin protein of influenza virus[23] and complement component C3 (ref. 24). Although the mechanism for IL-1 processing is unknown, it is tempting to speculate that this region serves as a proteolytic processing site to yield an intermediate polypeptide from which biologically active fragments are produced by further proteolytic cleavage. The segment following the multiple basic residues is less conserved in the three molecules, but in all cases, this segment (− in Fig. 5*b*) contains many acidic amino acids. No basic residues are found in this region, except just before the amino terminus of the active IL-1 segments. Such a negatively charged region, present in all three molecules, probably has a conserved structural or functional role. The rest of the sequence comprises the processed active M_r 17,500 IL-1 region.

Discussion

We have isolated cDNA clones representing two distinct but distantly related forms of human IL-1, IL-1α and IL-1β, from LPS-stimulated macrophage RNA. Although the nucleotide sequence of the cDNA clones predicts primary translation products of M_r 30,606 and 30,749 for IL-1α and IL-1β, respectively, we have shown that the C-terminal 159 and 153 amino acids are sufficient for the production of IL-1 biological activity. Previous reports have characterized IL-1 activities as having

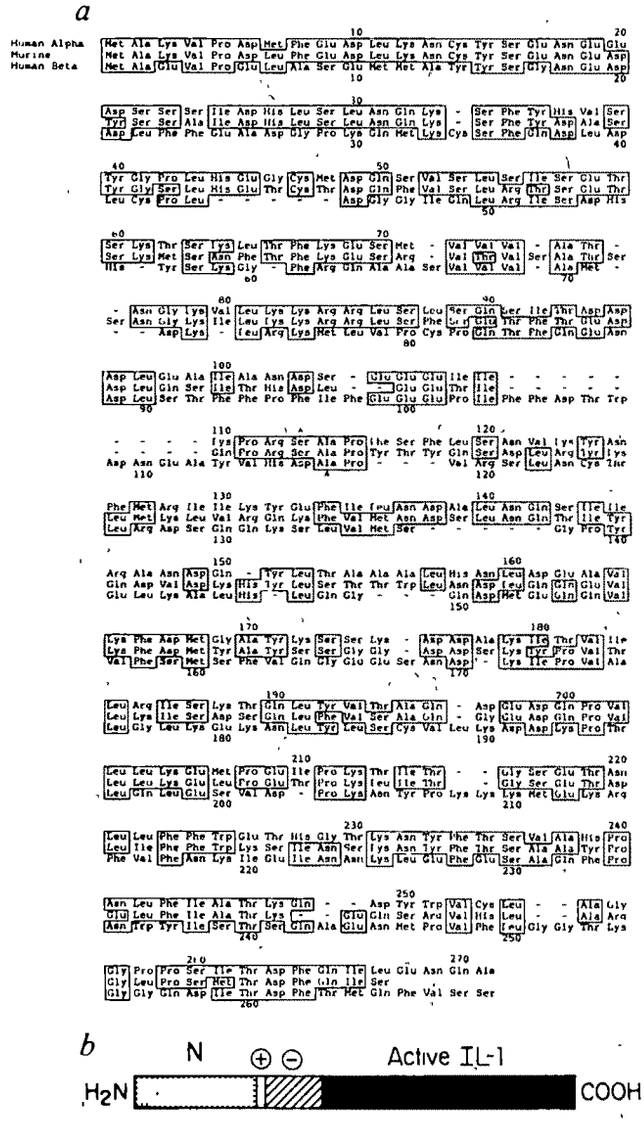

Fig. 5 *a*, Alignment of human IL-1α, murine IL-1[10] and human IL-1β amino-acid sequences. Numbering begins at the presumed initiator methionine; numbering above the top row is for IL-1α; that below the bottom row is for IL-1β. Boxed residues indicate identities between two or more of the sequences. Star above Ser 113, presumed NH_2-terminus of IL-1α; star below Ala 117 of IL-1β NH_2-terminus as defined by protein sequencing. Alignment presented was determined by a combination of computerized methods[20,46], hydrophilicity analysis[47] and visual inspection. *b*, Schematic representation of the common features of IL-1 polypeptides. Stippled box (N), N-terminal conserved region from Met 1 to Gly 78 in IL-1α, or to Asp 72 in IL-1β. Small open box (+), multiple basic region (Lys 79–Arg 85 in IL-1α, or Lys 73–Lys 76 in IL-1β). Hatched box (−), negatively charged region (Leu 86–Arg 112 in IL-1α, or Met 77–Asp 116 in IL-1β). Closed box ('Active IL-1'), C-terminal region of the primary translation product representing the extent of the processed, active M_r 17,500 IL-1 (Ser 113–Ala 271 for IL-1α; Ala 117–Ser 269 for IL-1β).

M_rs of ~30,000 and 17,000. Our results resolve this inconsistency and support the concept that human IL-1s are synthesized as higher M_r precursors that are proteolytically cleaved to M_r 17,500 active forms, as has been proposed for murine IL-1[8]. However, we have not yet defined all of the naturally occurring, biologically active forms of IL-1α and IL-1β; this will require the generation of specific antisera against these molecules.

An interesting difference between IL-1α and IL-1β is that the primary translation product of IL-1α seems to be biologically active, judged by the production of IL-1 activity by hybrid-selected IL-1α mRNA in a rabbit reticulocyte lysate (Table 1). In contrast, hybrid-selected IL-1β mRNA was not biologically active under the same conditions, even though a protein corresponding to the IL-1β primary translation product could be seen clearly when the hybrid-selected IL-1β mRNA was translated in a reticulocyte lysate supplemented with ^{35}S-methionine and analysed on an SDS-polyacrylamide gel (data not shown). It is also possible that the primary translation product of IL-1α is more efficiently cleaved to a smaller active form. This suggestion is supported by the presence of a basic amino acid immediately before Ser 113 that might be a cleavage site for a trypsin-like protease.

Unlike other secreted proteins, IL-1α and IL-1β do not contain a stretch of hydrophobic amino acids, either at the N-terminus or internally, raising the possibility that IL-1 is not actively secreted by macrophages, but is released by damaged cells[25]. This conclusion is supported by the inefficient release of IL-1 activity by *Xenopus* oocytes injected with IL-1 mRNA or by COS-7 monkey kidney cells transfected with IL-1 expression vectors (data not shown). Alternatively, macrophages may export IL-1 by a mechanism distinct from that described for other secretory proteins.

Recently, Auron *et al.* reported the sequence of a cDNA clone that is very similar to IL-1β[11]. There are seven nucleotide substitutions between the two sequences, five of which are silent changes. Plasmid pIL-1-14 has an adenine instead of a guanine at nucleotide 16, changing lysine to glutamic acid, and lacks the upstream, out of frame, potential initiation codon found in the sequence of Auron *et al.* (position −23 in Fig. 2). All the nucleotide substitutions in our sequences have been verified by sequencing other IL-1β cDNA clones, and presumably represent allelic differences or reverse transcriptase errors. Van Damme *et al.* have recently described the N-terminal amino acid sequence of a secreted factor with strong homology to the predicted amino acid sequence of the central region of the IL-1β cDNA clone[48].

It is striking that two distinct molecules should mediate the induction of IL-2 synthesis. Whether they share all the biological activities previously attributed to IL-1 is under investigation. It will now be possible to determine if both IL-1α and IL-1β bind to the same receptor, analogous to the binding of the structurally distinct epidermal growth factor (EGF) and transforming growth factor-α molecules to the EGF receptor[26]. Resolution of these issues should increase our understanding of the biological role of IL-1 in immunity and inflammation.

We thank Toni Read and Judy Byce for the preparation of the manuscript and Steve Gimpel, Janis Wignall, Kate McKereghan, Theresa Washkewicz, Catherine Grubin, Reiling Liao, Shelley Berg, Kurt Shanebeck and Steve Hartman for technical assistance. This work was made possible by collaboration between Immunex Corporation and Syntex (USA) Inc.

† Astronomy Program, University of Maryland, College Park, Maryland 20742, USA

The absorption line at 26 MHz observed by Konovalenko and Sodin[1] towards Cas A was interpreted by Blake *et al.*[2] as the 631α recombination line due to carbon or heavier elements. This was confirmed subsequently by Konovalenko and Sodin[3], who detected the 640α line at the same optical depth as the 631α line, within error limits. These lines represent the highest excited states yet detected in interstellar gas and could provide[4] a unique diagnostic of conditions in diffuse clouds if observed over a range of frequencies. We now report new observations of these lines carried out near 26, 38, 52 and 68 MHz using the National Radio Astronomy Observatory (NRAO) 91-m telescope at Green Bank. We detected absorption lines at all these frequencies, with a striking fourfold increase in width towards low frequencies due to collisional or radiation broadening. Assuming that these are recombination lines of carbon, the observed radial velocity corresponds well with that of the H I, OH, NH_3 and H_2CO absorption features that originate in the Perseus arm in the same direction[5-8].

The 68- and 52-MHz observations were made in July 1984, using the 50-80-MHz tunable dipole on the travelling feed system. The 38- and 25-MHz observations were made in August 1984 using a broadband 20-50-MHz dipole especially made for this experiment and mounted on the travelling feed, which is capable of tracking a source for 76 sec δ minutes, where δ is the declination. In the frequency range of these observations, the system temperature was dominated by Cas A and the galactic background. At each of the four frequencies, two or three nearby transitions in carefully chosen interference-free bands were observed simultaneously. The 384-channel autocorrelation receiver was split into four independent spectrometers of 96 channels each, providing a frequency resolution of 0.98 kHz at the two higher and 0.49 kHz at the two lower frequencies. Reference spectra were measured by switching to a noise source which was adjusted to match the total system temperature when the antenna was pointed to Cas A.

Table 1 Observed line parameters

Frequency (MHz)	V_{LSR} (km s^{-1})	T_L/T_C ($\times 10^3$)	ΔV (km s^{-1})	$\int \tau\, d\nu$ (s^{-1})
26	−45±5	−3.8±0.5	32.9±2.1	11.6±0.7
38	−49±2	−3.5±0.4	17.9±0.9	8.4±0.5
52	−49±2	−3.5±0.4	13.0±0.7	8.6±0.5
68	−48±2	−2.9±0.6	8.3±0.9	5.9±0.8

Errors quoted are 1σ values. V_{LSR} is the radial velocity with respect to the local standard of rest, T_L and T_C are the line and continuum antenna temperatures respectively; ΔV is the full linewidth at half maximum intensity; $\int \tau\, d\nu$ is the optical depth integrated over the line.

The spectra obtained after removing a linear baseline at each of the four frequencies are shown in Fig. 1. The recombination line is seen in absorption at all the four frequencies at the velocity corresponding to the Perseus arm. In the spectra in Fig. 1 there are suggestions, at least at the three lower frequencies, that the absorption line may be present at the velocities of both −47 and −39 km s^{-1} at which H I absorption is seen in the Perseus arm[5]. However, we find no evidence in our spectra of a line at 0 km s^{-1} corresponding to the Orion arm absorption, and no hydrogen recombination lines. The line parameters obtained by fitting a single gaussian to each of the observed spectra are given in Table 1. As Cas A dominates the system temperature at these frequencies, the line-to-continuum ratio plotted in Fig. 1 and given in Table 1 is approximately equal to the observed optical depth.

All high-frequency observations (mainly towards H II regions) show recombination lines of hydrogen or heavier elements only in emission. However, there are good reasons for expecting recombination lines to be seen in absorption at very low frequencies particularly from cold gas[2] and in the presence of strong background radiation. At very large n (the principal quantum number) electron collisions dominate (as among free electrons) and therefore maintain thermalization of the populations. It is only at lower n (and correspondingly higher frequencies) that radiative processes begin to dominate and the excitation temperature moves away from the kinetic temperature of

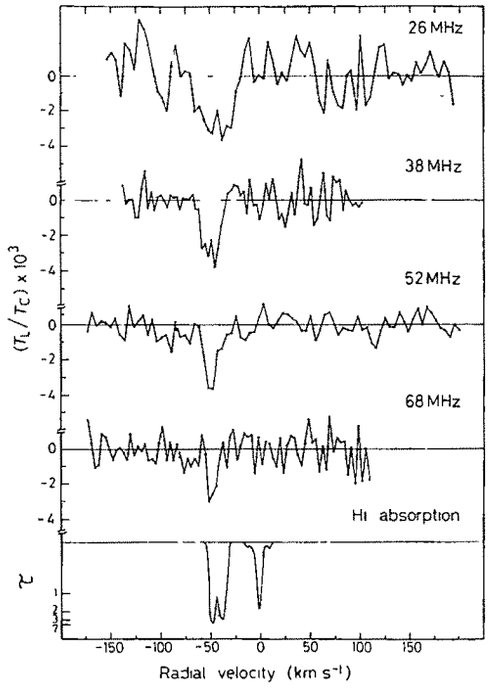

Fig. 1 Recombination line spectra towards Cas A observed at four frequencies At each frequency the spectrum is an average of two or three nearby transitions that were observed simultaneously. These transitions are 26 MHz, 629α and 634α; 38 MHz, 554α and 556α; 52 MHz, 497α, 501α and 503α; 68 MHz, 456α, 457α and 458α. The effective integration times for the four frequencies are 4.4, 10.7, 10.5 and 9.6 h respectively. The H I absorption spectrum is from ref. 5.

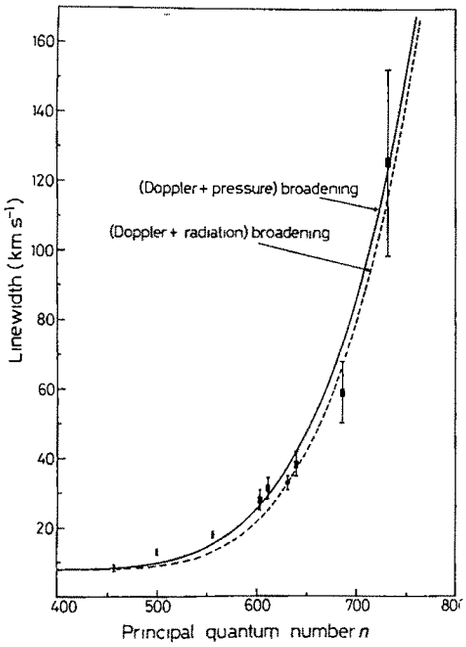

Fig. 2 Calculated and observed variation of line width (FWHM). ●, Present observations; ■, data from ref. 12. Pressure broadening is calculated for $T_e = 50$ K and $N_e = 0.18$ cm^{-3} and for radiation broadening a brightness temperature $T_R = 2{,}000$ K at 100 MHz ($\alpha = -2.6$) was used. A Doppler component of 8 km s^{-1} is assumed for both cases. The relevant formulas are taken from ref. 13.

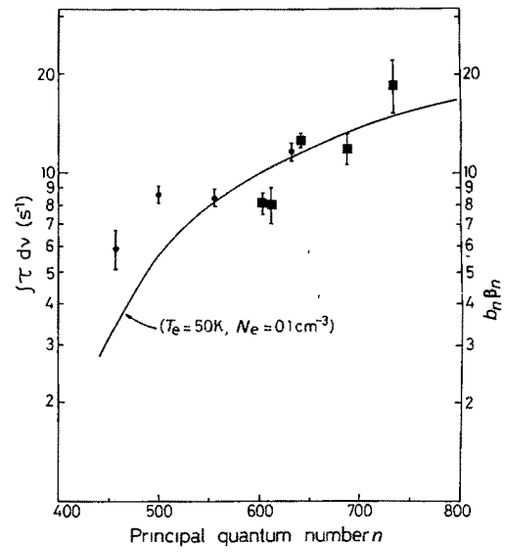

Fig. 3 The observed variation of integrated line intensity. The quantity $b_n\beta_n$ (solid curve) taken from ref. 9 is normalized to a value of 10 at $n = 600$. This quantity which is proportional to the net optical depth was calculated by Walmsley and Watson[9] based on a dielectronic recombination process. ●, Present observations; ■, data from ref. 12.

the gas, towards negative values, so that the line can never be seen in absorption irrespective of the background radiation. The turnover frequency will, however, depend on the density and temperature of the gas and the populating mechanism[9] for the species of atom in question.

As pointed out by Blake *et al.*[2], the identification of the heavy element responsible for the line towards Cas A cannot be made on the basis of frequency alone. It is most likely to be carbon if it originates in cold gas. Alternatively, it could be due to heavier elements such as calcium or magnesium if located in hot gas[2,10,11]. In the present case, however, the agreement in velocity with the H I and molecular absorption features strongly favours cold dense clouds as the site of absorption, and carbon as the element in question.

The observed width of the line at 68 and 52 MHz is similar to that of the H I absorption line. The width, in velocity units, increases by nearly a factor of four at 26 MHz. This line has now been observed down to 16.7 MHz by Konovalenko[12] and the width increases even more dramatically (Fig. 2), which clearly indicates pressure and/or radiation broadening. Using the formula given by Shaver[13] for the collisional width at low temperatures we infer an upper limit of 0.2 cm^{-3} for the electron density of the gas responsible for the observed lines, assuming a temperature of 50 K. If the carbon in this cloud has a cosmic abundance ($C/H = 3 \times 10^{-4}$) and all of it is ionized, then this implies an upper limit to the hydrogen density of 600 cm^{-3}. This is consistent with the upper limit to the H I density obtained from the measured column density and the minimum size of the cloud implied by its high H I optical depth. From consideration of radiation broadening[13], we infer an upper limit of 2,000 K (at 100 MHz) for the ambient brightness temperature for the recombination line gas (see Fig. 2). This further implies a lower limit of 150 pc for the distance of the absorbing gas from Cas A, if we take the flux of Cas A at 100 MHz to be 15,000 Jy (ref. 14) and its distance and linear size to be 4 kpc and 5 pc, respectively.

At temperatures of 50–100 K, which are typical for H I clouds, calculations by Walmsley and Watson[4,9] show that dielectronic-like recombination on to carbon could be an important populating mechanism. This predicts an enhanced absorption at low frequencies and a variation of line strength as a function of frequency which depends on the electron density in the gas. At low electron densities ($N_e \sim 0.01$ cm^{-3}) a steep decrease in line strength from 25 to 100 MHz is predicted. From Table 1, although the observed peak optical depth in the line remains nearly constant in the frequency range 68–26 MHz, the integrated absorption ($\int \tau \, d\nu$) increases roughly by a factor of 2. If the dielectronic recombination process is operating, then the observed variation of the total line strength indicates an electron density of ~0.1 cm^{-3} (see Fig. 3) and rules out much lower densities.

Alternatively, these lines may be formed by carbon associated with dense molecular clouds rather than by carbon associated with more widely distributed H I. Batrla *et al.*[7] have observed two such clouds in H_2CO absorption against Cas A, each with a diameter of about 1 arc min and with velocities of −39 and −47 km s^{-1} respectively. These are foreground clouds in the Perseus arm which cover only a few per cent of the solid angle subtended by Cas A. If the low-frequency absorption lines are formed in the molecular clouds, then the true optical depths of these lines would be 20–30 times higher than the average optical depths that we observe.

It must be possible to observe these highly excited lines in many other directions in the galactic plane. At these low frequencies, the non-thermal galactic radiation can provide the background continuum and the presence of a discrete background source may not be necessary for the detection of the lines. The present observations have indicated that recombination lines below 100 MHz will be an important diagnostic of the interstellar medium as was emphasized by Shaver[13].

We thank Wes Sizemore, Bill Brundage and Bob Vance for technical assistance, Rick Fisher and Harry Payne for valuable advice, the NRAO staff for quickly fabricating the 20–50 MHz feed and receiver, and George Seielstad for making available extra telescope time at short notice. Nils Odegard helped us with the observations and Peter Shaver suggested the radiation broadening. W.C.E. was partly supported by the NSF under grant AST-82-15463. The NRAO is operated by the Associated Universities Inc. under contract with the NSF.

Analytical solution for the effect of increasing CO_2 on global mean temperature

T. M. L. Wigley

Increasing atmospheric carbon dioxide concentration is expected to cause substantial changes in climate[1]. Recent model studies suggest that the equilibrium warming for a CO_2 doubling ($\Delta T_{2\times}$) is about 3–4 °C[2–4]. Observational data show that the globe has warmed by about 0.5 °C over the past 100 years[5,6]. Are these two results compatible? To answer this question due account must be taken of oceanic thermal inertia effects, which can significantly slow the response of the climate system to external forcing. The main controlling parameters are the effective diffusivity of the ocean below the upper mixed layer (κ) and the climate sensitivity (defined by $\Delta T_{2\times}$). Previous analyses of this problem have considered only limited ranges of these parameters. Here we present a more general analysis of two cases, forcing by a step function change in CO_2 concentration and by a steady CO_2 increase. The former case may be characterized by a response time which we show is strongly dependent on both κ and $\Delta T_{2\times}$. In the latter case the damped response means that, at any given time, the climate system may be quite far removed from its equilibrium with the prevailing CO_2 level. In earlier work this equilibrium has been expressed as a lag time, but we show this to be misleading because of the sensitivity of the lag to the history of past CO_2 variations. Since both the lag and the degree of disequilibrium are strongly dependent on κ and $\Delta T_{2\times}$, and because of uncertainties in the pre-industrial CO_2 level, the observed global warming over the past 100 years can be shown to be compatible with a wide range of CO_2-doubling temperature changes.

We use an energy balance climate model consisting of two atmospheric boxes, one over land with zero heat capacity, and the other over an oceanic mixed layer coupled to a diffusive deeper ocean (compare refs 7–9). On timescales relevant to CO_2 forcing, the atmosphere may be assumed to be in equilibrium with the underlying surface. The model is then described by

$$\Delta T_L = \Delta T_{aL} = \frac{f\lambda \Delta T_i + k\Delta T_{aO}}{f\lambda + k} \quad (1)$$

$$\Delta T_{aO} = \frac{(f(1-f)\lambda + k)\lambda \Delta T_i + k_{as}(1-f)(f\lambda + k)\Delta T}{(f(1-f)\lambda + k)\lambda + k_{as}(1-f)(f\lambda + k)} \quad (2)$$

$$C_m \frac{d\Delta T}{dt} = \Delta Q - \lambda \Delta T - \Delta F \quad (3)$$

where ΔT_L, ΔT_{aL}, ΔT_{aO} and $\Delta T(t)$ are temperature changes for the land, atmosphere over land, atmosphere over ocean and oceanic mixed layer induced by a change in thermal forcing $\Delta Q(t)$, f is the fraction of the globe covered by land ($f \approx 0.29$), λ is the climate feedback parameter[10], k is a land-ocean heat transfer coefficient, k_{as} is an air-sea heat exchange coefficient, and $\Delta T_i(t)$ is the instantaneous equilibrium temperature change

$$\Delta T_i = \frac{\Delta Q}{\lambda} \approx \Delta T_{2\times} \frac{\ln(C/C_0)}{\ln 2} \quad (4)$$

for CO_2 change from C_0 to $C(t)$ (ref. 11). In equation (3), C_m is the effective bulk heat capacity ($C_m = \gamma \rho c h$) where

$$\gamma = \frac{(1-f)(k+\lambda f)}{k+\lambda f(1-f)} + \frac{\lambda}{k_{as}} \quad (5)$$

and h is the depth of the mixed layer in which the density and specific heat capacity are ρ and c respectively. ΔF is the change in heat flux at the bottom of the mixed layer ($z = 0$)

$$\Delta F = -\gamma \rho c \kappa \left(\frac{\partial \Delta T_0}{\partial z}\right)_{z=0} \quad (6)$$

where κ is the thermal diffusivity of the deep ocean ($z > 0$) whose temperature change due to ΔQ is $\Delta T_0(z, t)$. z is depth below the bottom of the mixed layer. ΔT_0 is determined by

$$\frac{\partial \Delta T_0}{\partial t} = \kappa \frac{\partial^2 \Delta T_0}{\partial z^2} \quad (7)$$

With the initial condition $\Delta T_0(z, 0) = 0$ and the boundary conditions $\Delta T_0(0, t) = \Delta T(t)$ and $\Delta T_0(z, t) \to 0$ as $z \to \infty$, the solution to equation (7) can be approximated to give

$$\Delta F = \gamma \mu \rho c h \frac{\Delta T}{\sqrt{\tau_d t}} \quad (8)$$

where $\tau_d = \pi h^2/\kappa$ is a characteristic time for exchange between the mixed layer and the deeper ocean; τ_d varies between 5 and 10 yr for realistic values of h and κ. The constant μ can be determined by comparing results from an analytical solution of equation (9) below, with those from a full numerical integration of the coupled equations (3), (6) and (7). The value of μ depends to some degree on the assumed forcing ($\Delta Q(t)$), but is insensitive to variations in κ, λ and h. The validity of this approximation is discussed below (see Table 1).

Since $\lambda \ll k_{as}$ (ref. 10), $\Delta T_{aO} \approx \Delta T$ in accord with observations (ref. 6), and the λ/k_{as} term in the expression for γ may be ignored. Two limiting cases give the bounds on γ. For $k = 0$ (no land-sea heat exchange), $\gamma = 1$, which also corresponds to an ocean-covered Earth. For $k \to \infty$ (infinitely fast land-sea heat exchange), $\gamma = 1 - f \approx 0.71$, which corresponds to the fraction of the globe covered by ocean. For realistic values of λ and k, γ lies between 0.72 and 0.75.

Substitution of equation (8) into equation (3) gives an ordinary differential equation describing $\Delta T(t)$:

$$\gamma \frac{d\Delta T}{dt} + \Delta T \left\{\frac{1}{\tau_f} + \frac{\mu\gamma}{\sqrt{\tau_d t}}\right\} = \frac{\Delta Q}{\rho c h} \quad (9)$$

where $\tau_f = \rho c h/\lambda$ is the response time for step-function forcing of a thermally isolated mixed layer with no land-sea heat exchange, that is, $\Delta F = 0$ and $\gamma = 1$. τ_f ranges between 4 and 13 yr for realistic values of h and λ.

Equation (9) can be solved exactly for a number of different forms of the forcing function ΔQ. We will consider $\Delta Q = a$, giving the transient response to a step-function CO_2 change (the 'switch-on' experiment[12]), and $\Delta Q = bt \exp(\alpha t)$; a, b and α are arbitrary constants. Since the radiative response is approximately proportional to the logarithm of the concentration (ref. 11 and equation (4) above), $\alpha = 0$ corresponds to an exponentially increasing CO_2 concentration while $\alpha \neq 0$, for appropriate b and α, corresponds closely to observed changes of CO_2 over the past 130 yr.

For the switch-on experiment, ΔT tends to ΔT_e for large t where

$$\Delta T_e = a/\lambda \tag{10}$$

The solution to equation (9) is then

$$\frac{\Delta T}{\Delta T_e} = 1 - e^{-W} - 2G \tag{11}$$

where $G = G(Z, N) = N[D(Z+N) - e^{-W}D(N)]$, $W = W(Z, N) = Z^2 + 2NZ$, $Z^2 = t/(\gamma\tau_f)$ and $N^2 = \gamma\mu^2\tau_f/\tau_d$. In $G(Z, N)$, D is Dawson's integral[13], $D(z) = e^{-z^2}\int_0^z e^{u^2}\,du$. The parameter N depends on μ which takes the value 1.4 for step-function forcing.

The switch-on case is important because is has been used by a number of investigators to study the transient response characteristics of the climate system. The speed of response, and the influence of oceanic thermal inertia, can be characterized by the e-folding time, τ_e, defined by $\Delta T(\tau_e) = (1 - e^{-1})\Delta T_e$. If $Z_e^2 = \tau_e/(\gamma\tau_f)$, then τ_e is determined by

$$e^{-W_e} + 2G(Z_e, N) = e^{-1} \tag{12}$$

For large N the solution is $Z_e \approx (e-1)N$ (using $D(u) \sim 1/2u$), an excellent approximation (error in Z_e less than 5%) for $N > 1.5$, that is, for almost all values of N likely to be encountered. Hence

$$\tau_e \approx \gamma^2\mu^2(e-1)^2(\tau_f)^2/\tau_d \approx 47.8\gamma^2\mu^2\kappa/\lambda^2 \tag{13}$$

for κ in $cm^2\,s^{-1}$ and λ in $Wm^{-2}\,K^{-1}$. If we consider the case of a step-function doubling of CO_2 concentration, then (from equation (10)) $\lambda = \Delta Q_{2\times}/\Delta T_{2\times}$ where $\Delta Q_{2\times} \approx 4.3\ Wm^{-2}$ (ref. 3). Since $\mu = 1.4$, equation (13) becomes

$$\tau_e \approx 5.08\gamma^2\kappa(\Delta T_{2\times})^2 \tag{14}$$

τ_e is independent of the mixed layer depth, h. This analytical result can be compared with the numerical calculations of Hansen *et al.*[3]. For $\kappa = 1\ cm^2\,s^{-1}$ and $\Delta T_{2\times} = 4.2, 3.0, 2.0\,°C$, these authors obtain $\tau_e = 102, 55, 27$ yr using $\gamma = 1$. Equation (14) gives $\tau_e = 90, 46, 20$ yr, in close agreement. For $\gamma = 0.75$ (see above), τ_e ranges between 6 and 174 yr for $\kappa = 1$–$3\ cm^2\,s^{-1}$ and $\Delta T_{2\times} = 1.5$–$4.5\,°C$. There is thus a considerable range of uncertainty in τ_e resulting from uncertainties in the magnitude of the CO_2-doubling temperature change and in sub-mixed-layer mixing.

The e-folding time demonstrates that oceanic thermal inertia has a significant effect in determining the response of the climate system to external forcing. However, the results of a switch-on experiment are transferable to the case of steadily increasing CO_2 concentration only through a convolution integral[4]. We therefore consider the 'continuous increase' experiment with time-dependent forcing.

Forcing of the form $\Delta Q = bt\exp(\alpha t)$ corresponds to CO_2 variations given by

$$C(t) = C_0\exp(Bt\,e^{\alpha t}) \tag{15}$$

where C_0 is the initial, pre-industrial concentration and $B = b\ln 2/\Delta Q_{2\times}$. Observed CO_2 changes can be fitted to this form. For example, if $C_0 = 270$ parts per million by volume (p.p.m.v.) in 1850[14], and C = 315 p.p.m.v. in 1958 and 338 p.p.m.v. in 1980[15], then $B = 5.59\ 10^{-4}$ and $\alpha = 8.69\ 10^{-3}\ yr^{-1}$.

The solution to equation (9) for $\Delta Q = bt\exp(\alpha t)$ is

$$\frac{\Delta T}{\Delta T_i} = \frac{\gamma\tau_f}{\beta^2 t}[\tilde{Z}^2 - \tilde{N}\tilde{Z} - (1-\tilde{N}^2)(1-e^{-\tilde{W}}) + (3-2\tilde{N}^2)\tilde{G}] \tag{16}$$

where ΔT_i is the instantaneous equilibrium temperature change at time t (equation (4)), $\beta = 1 + \alpha\gamma\tau_f$, $\tilde{Z}^2 = \beta Z^2$, $\tilde{N}^2 = N^2/\beta$, $\tilde{W} = W(\tilde{Z}, \tilde{N})$ and $\tilde{G} = G(\tilde{Z}, \tilde{N})$. The case $\beta = 1$ (that is, $\alpha = 0$, $\tilde{W} \equiv W$, $\tilde{G} \equiv G$) corresponds to linear thermal forcing due to an exponentially increasing CO_2 concentration. The departure of $\Delta T/\Delta T_i$ from unity is a measure of the degree of disequilibrium due to oceanic thermal inertia effects.

Since the initial CO_2 level and the history of past CO_2 variations appear in equation (16) only through the α term in β, and since β is always close to 1, the degree of disequilibrium must be insensitive to the details of past CO_2 changes. This is demonstrated in Table 1. Insensitivity to the initial CO_2 level can be seen by comparing $\Delta T/\Delta T_i$ values for various values of C_0, and insensitivity to the CO_2 history for given C_0 can be seen by the proximity of $\Delta T/\Delta T_{lin}$ (where ΔT_{lin} corresponds to ΔT for $\alpha = 0$) to unity. The degree of disequilibrium, however, does vary markedly with κ and $\Delta T_{2\times}$.

Equation (16) implies that the response $\Delta T(t)$ lags behind the instantaneous equilibrium response by a time-varying amount L which can be defined by

$$\Delta T(t) = \Delta T_i(t - L) \tag{17}$$

It can easily be shown that

$$\frac{\Delta T(t)}{\Delta T_i(t)} = \left(1 - \frac{L}{t}\right)e^{-\alpha L} \tag{18}$$

so that, for $\alpha \geq 0$, L is a maximum in the linear forcing case. For this case ($\alpha = 0$) $L(= L_{lin})$ can be related to the switch-on e-folding time τ_e (equation (14)) by substituting equation (16) into (18) and using $D(u) \sim 1/2u$:

$$L_{lin} \approx 0.91\sqrt{t\tau_e} - 0.84\tau_e(1 - 0.91\xi) + \gamma\tau_f(1 - 1.37\xi) \tag{19}$$

where $\xi = (0.91 + \sqrt{t/\tau_e})^{-1}$. L_{lin} is therefore independent of the initial CO_2 level and the timescale for CO_2 increase (see Table 1).

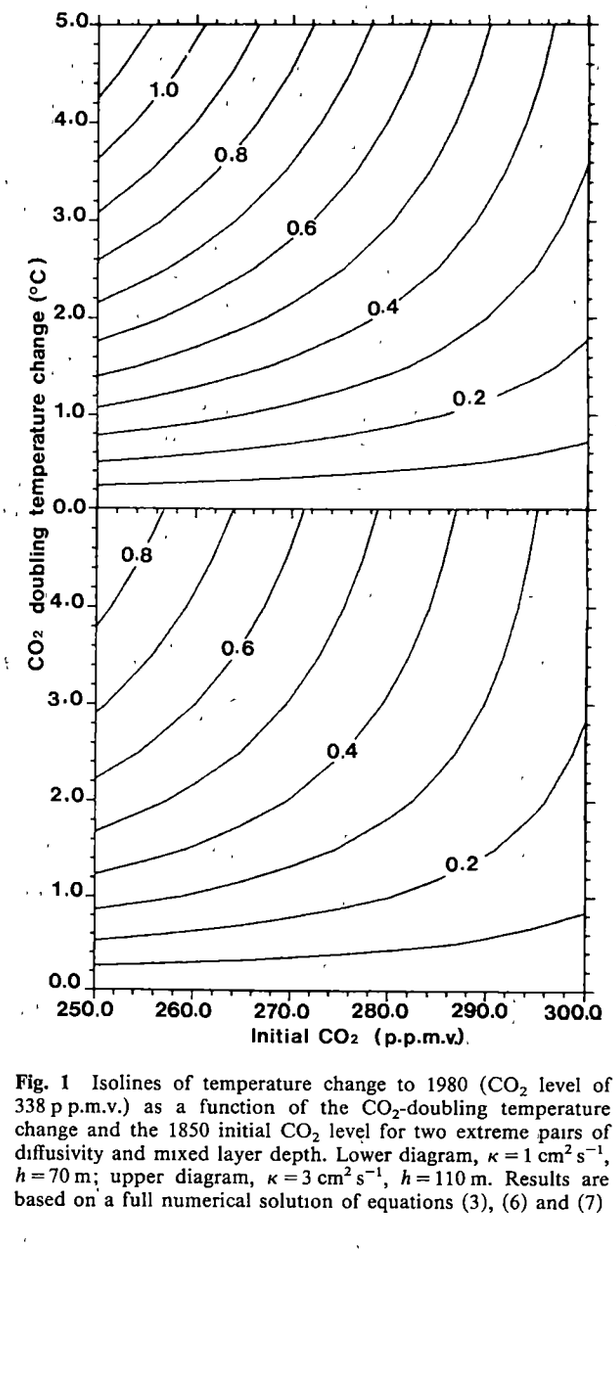

Fig. 1 Isolines of temperature change to 1980 (CO_2 level of 338 p p.m.v.) as a function of the CO_2-doubling temperature change and the 1850 initial CO_2 level for two extreme pairs of diffusivity and mixed layer depth. Lower diagram, $\kappa = 1\ cm^2\,s^{-1}$, $h = 70$ m; upper diagram, $\kappa = 3\ cm^2\,s^{-1}$, $h = 110$ m. Results are based on a full numerical solution of equations (3), (6) and (7)

For $\alpha \neq 0$, however, the lag is strongly dependent on α and C_0, the parameters characterizing the history of past CO_2 variations. The sensitivity to α can be seen by comparing L with L_{lin} in Table 1, while the sensitivity to C_0 can be seen directly in this table. Because of this, and because C_0 is uncertain[14], the lag time is not a particularly good parameter to use as an indicator of oceanic thermal inertia effects. Table 1 also shows that L is strongly dependent on κ and $\Delta T_{2\times}$, the values of which are also uncertain.

The most important result shown in Table 1 is the wide range of uncertainty in the disequilibrium ratio, $\Delta T/\Delta T_1$, 0.42 to 0.79 for $C_0 = 270$ p.p.m.v. $\Delta T/\Delta T_1$ decreases as $\Delta T_{2\times}$ increases, in accord with the results of Siegenthaler and Oeschger[9] (who used $\Delta T_{2\times} = 2.0$ °C and 3.2 °C with $\kappa = 1$ cm^2 s^{-1}), and as κ increases, in accord with Hansen *et al.*[3] (who used $\kappa = 1$ and 2 cm^2 s^{-1} with $\Delta T_{2\times} = 4.2$ °C). Hansen *et al.*'s values of $\Delta T/\Delta T_1$ are noticeably less than ours because they used $\gamma = 1$ If the climate sensitivity is as high as recent model results suggest (refs 2-4) then $\Delta T/\Delta T_1 \approx 0.5$ and a substantial future warming must occur even in the absence of further CO_2 increases, a point already noted by Hansen *et al.*[3] and by Siegenthaler and Oeschger[9].

The overall uncertainty is further illustrated in Fig. 1 which shows $\Delta T(1980)$ as a function of initial CO_2 level and CO_2-doubling temperature change. The warming depends strongly on the initial CO_2 level. ΔT values in Fig 1 are compatible with the observed global mean warming of around 0.5 °C over the past 100 yr, especially when one considers the uncertainties in the observational record[5,6]. For $260 < C_0 < 280$ p.p m.v. (ref. 14) and $1.5 < \Delta T_{2\times} < 4.5$ °C (ref. 1), ΔT ranges between 0.26 and 0.96 °C. If observed temperature changes in the range 0.4–0 6 °C were to be explained solely in terms of CO_2 changes then, for $260 < C_0 < 280$ p.p.m.v., the implied $\Delta T_{2\times}$ range is 1.3–11.5 °C. A consideration of transient response effects, therefore, helps to remove the apparent conflict noted in ref. 16 between recent model results[2-4] and observations[5,6] (a point noted by Hansen *et al.*[3]). The high upper limit to the implied $\Delta T_{2\times}$ value (that is, 11.5 °C, corresponding to $\Delta T = 0\,6$ °C, $C_0 = 280$ p.p.m.v., $\kappa = 3$ cm^2 s^{-1}, $h = 110$ m) requires comment. $\Delta T_{2\times}$ affects $\Delta T(t)$ in two competing ways; through $\Delta T_1(t)$, which increases with increasing $\Delta T_{2\times}$, and through the disequilibrium ratio, $\Delta T/\Delta T_1$, which decreases as ΔT_{2x} increases. Therefore, as Fig. 1 shows, the 1980 value of $\partial \Delta T/\partial \Delta T_{2\times}$ becomes small for large $\Delta T_{2\times}$ (particularly for large κ), so that $\Delta T(1980)$ can be quite insensitive to changes in $\Delta T_{2\times}$. The 11.5 °C upper limit for $\Delta T_{2\times}$ is in this insensitive region, but its value is sensitive to C_0 and κ, and to the chosen history of CO_2 variations. Thus, it is the qualitative conclusion that a large value of $\Delta T_{2\times}$ could be consistent with observed ΔT values which is important, rather than the specific numerical value obtained here.

An additional source of uncertainty becomes evident retrospectively from the analytical solution. Because of the lag in the response due to the thermal inertia of the oceans, we can be fairly sure that the climate system was not initially in equilibrium as we have assumed in our calculations. The subsequent warming does depend on whether the initial global-mean temperature was above or below the equilibrium temperature, that is on the thermal forcing history before 1850. In the absence of information about the degree or even direction of the initial disequilibrium, we must neglect this confounding issue.

We have considered only CO_2 in defining the thermal forcing function $\Delta Q(t)$. Recent increases in the concentrations of other trace gases (such as methane and chlorofluorocarbons) may have added noticeably to the forcing[3,17], contributing perhaps as much as 0.2 °C to the overall warming since 1960[18]. The CO_2 contribution to the observed global mean warming of 0.4–0.6 °C over the past 100 yr would therefore be only 0.2–0.4 °C. For $260 < C_0 < 280$ p.p.m.v., this implies a $\Delta T_{2\times}$ range of only 0.6–3.1 °C (see Fig. 1). Recent ice-core evidence, however, suggests that the 260–280 p.p.m.v. initial CO_2 range may be too low. Neftal *et al.*[19] give new data with concentrations around 290 p.p.m.v. in the late nineteenth century. Initial levels of 270 and 290 p.p.m.v give $\Delta T(1980)$ values which differ by about 0.2 °C, largely compensating for the trace gas effect. This higher initial CO_2 level may, therefore, be necessary in order to ensure compatibility between model results and observations.

These results cannot be construed as proof of the detection of CO_2 effects on climate, although they do help to bring model results more in line with observations. Detection requires a statistically significant warming above the noise level of natural interannual and interdecadal temperature fluctuations[20,21], together with a convincing attribution of at least part of such warming to carbon dioxide. These statistical aspects, together with problems of data reliability and representativeness, and our present inadequate understanding of the processes other than CO_2 that can cause global climate change, make it impossible to attribute the observed warming unequivocally to CO_2. In fact, transient response effects make detection even more difficult because, by lowering the signal expected at any given time, the signal-to-noise ratio is correspondingly lowered. The insensitivity of $\Delta T(1980)$ to $\Delta T_{2\times}$ for large $\Delta T_{2\times}$ means that it may be very difficult to determine $\Delta T_{2\times}$ from observational data.

Table 1 Disequilibrium ratios and lags (yr)

	C_0	250			270			290

	L_{lin}	51(51)	61(61)	67(67)	51(51)	61(61)	67(67)	51(51)	61(61)	67(67)

Values represent variations in the disequilibrium ratio ($\Delta T/\Delta T_1$) and the lag (L) in 1980 for $\gamma = 0.71$ and various values of the diffusivity ($\kappa = 1$–3 cm^2 s^{-1}, see refs 4, 9, 22, 23), the CO_2-doubling temperature change ($\Delta T_{2\times} = 1.5$–4.5 K, see ref. 1) and the initial (1850) CO_2 level ($C_0 = 250$–290 p.p.m.v., a range which spans the most likely range of 260–280 p p.m.v given in ref. 14) ΔT and L correspond to CO_2 variations given by equation (15) fitted through 315 p.p.m.v in 1958 and 338 p.p m.v. in 1980[15], while ΔT_{lin} and L_{lin} correspond to CO_2 variations given by equation (15) with $\alpha = 0$ fitted through 338 p p.m.v in 1980 (that is, to linear radiative forcing) ΔT and L are relatively insensitive to variations in h; $h = 70$m has been used here (ref. 3). The values shown are based on a full numerical solution of equations (3), (6) and (7), while the bracketed figures are those based on the approximate analytical solution (equation (16)) with $\mu = 2.2$ in the linear case and $\mu = 2.7$ otherwise. In the nonlinear case the optimum value of μ depends on C_0, but we have used the value appropriate to $C_0 = 270$ p.p.m.v. throughout.

We thank D. Vickers of Oregon State University, Climatic Research Institute and G Farmer of the University of East Anglia, Climatic Research Unit for programming assistance, and Jim Hansen for a constructive review. Methane flux from northern peatlands

Robert C. Harriss*, Eville Gorham†, Daniel I. Sebacher*, Karen B. Bartlett‡ & Patricia A. Flebbe*

The concentration of methane (CH_4) in the global troposphere is increasing. Ambient air measurements document an approximate rate of increase of 1–2% yr^{-1} over the past decade[1–4]. Measurements of CH_4 in air bubbles trapped in polar ice indicate that tropospheric concentrations of CH_4 several hundred years ago may have been ~45% of present levels[5–7]. To understand and assess possible causes of the atmospheric CH_4 increase requires improved quantitative knowledge of global sources and sinks of CH_4. Previous attempts to estimate sources of atmospheric CH_4, based on very few measurements, have suggested that natural and agricultural wetlands are major sources[8,9]. The major wetland regions of the world are in boreal, low Arctic and tropical ecosystems[10]. It is these regions, particularly in peatland habitats where major accumulations of organic materials occur under anaerobic conditions, that should be significant sources of global tropospheric CH_4. The most extensive peatlands in the world occur in the boreal taiga zone between ~45° and 65° N latitude. More than 95% of world peat resources occur in the Soviet Union, Canada, the United States, Sweden, Norway, Finland and the United Kingdom[10]. We report here the first survey of CH_4 flux from northern peatlands of the United States. Emission rates ranged from 0.003 to 1.94 g CH_4 m^{-2} day^{-1}, with half of these values between 0.1 and 0.4 g CH_4 m^{-2} day^{-1}. The frequency distribution is log normal (Fig. 1) and the mean emission rate is 0.337 g CH_4 m^{-2} day^{-1}. Such fluxes are higher than most values reported for other ecosystems, suggesting that northern peatlands may be an important source of global tropospheric CH_4.

In an effort to improve our understanding of wetlands as a source of atmospheric CH_4, which should aid in the interpretation of global distributions and trends, we developed a portable system for rapid, direct measurement of CH_4 flux in remote wetland environments. The system consists of a gas-filter-correlation (GFC) infrared detector[11] coupled to a controlled environment chamber. Flux measurements were made in a closed-chamber mode with air continuously recirculated from the sampling chamber over the surface peat and vegetation, then into the GFC and back to the chamber; CH_4 concentration was measured continuously. Continuous measurement of CH_4 in the chamber enables us to separate 'pulses' related to any human disturbance of the bog from the natural efflux. For a typical 15-min continuous sampling and analysis period, this system has a flux detection limit of 1×10^{-4} g CH_4 m^{-2} day^{-1}. Calibration was carried out in the field using certified CH_4 standards. Details of instrument design, calibration, and field testing are given elsewhere[11,12].

Our survey of CH_4 emissions from northern wetlands was conducted in August 1983, during daylight hours. Four sites were in the Marcell Experimental Forest, north-central Minnesota (47°32′ N, 93°28′ W), where a single watershed often consists of a central peatland surrounded by forested uplands. Characteristic plants of the Marcell fens and bogs are given by Boelter and Verry[13]. Upland soils over slightly calcareous glacial debris constitute 74% of the Marcell Forest surface, peatlands comprise 21%, and open water the remaining 5% (ref. 14). Peat deposits consist primarily of *Sphagnum* peat at the surface with woody, sedge, and aquatic plant residues at depth[15]. Three of our Marcell sites are perched ombrotrophic bogs; their water is derived almost entirely from precipitation (that is, WS-1, WS-2, and WS-4 in Table 1). Site WS-3 is a minerotrophic shrub/sedge fen; its water is derived primarily from groundwater. The hydrology and chemistry of these bogs have been studied in detail elsewhere[13]. The ombrotrophic bogs have low concentrations of dissolved ions, with a conductance 51 ± 13 μS cm^{-1} at 25 °C and an average *p*H of 3.6 ± 0.3. The minerotrophic fen (WS-3) has high concentrations of dissolved ions from reactions of groundwater with soil, conductance 125 ± 48 μS cm^{-1}, *p*H 6.5 ± 0.3 (ref. 14).

We also studied CH_4 flux from 21 separate sites in an area where a weakly minerotrophic fen surrounds a small ombrotrophic bog, 10.5 km west of Zerkel, Minnesota (47°10′ N, 95°24′ W). The vegetation includes a central pond with *Brasenia schreberi*, surrounded by a floating mat of *Carex lasiocarpa* and *Vaccinium macrocarpon*. The sedge mat is being invaded on its landward side by bog mosses such as *Sphagnum angustifolium*, *S subsecundum* and *S. magellanicum* and by the vascular plants *Vaccinium oxycoccus*, *Potentilla palustris*, *Dulichium arundinaceum* and *Scheuchzeria palustris*. Closer to the upland is a zone of low leatherleaf shrubs (*Chamaedaphne calyculata*) and several bog mosses, including *Sphagnum rubellum*, *S. magellanicum*, *S. papillosum*. *S. angustifolium* and *S. fuscum*, together with *Vaccinium oxycoccus*, *Scheuchzeria palustris*, and *Andromeda glaucophylla*. We also sampled ombrotrophic sites at this location inside and outside a small stand of black spruce (*Picea mariana*) associated with *Chamaedaphne calyculata*, *Ledum groenlandicum*, *Carex trisperma*, *Eriophorum spissum* and

Table 1 Methane flux from peatland sites in northern Minnesota

Site	No	CH_4 flux (g CH_4 m^{-2} day^{-1}) Average	Range
Marcell Experimental Forest			
WS-1 (bog)	3	0.156	0.127-0.206
WS-2 (bog)	9	0.047	0.019-0.174
WS-3 (fen)	3	0.004	0.003-0.005
WS-4 (bog)	6	0.194	0.033-0.468
Zerkel fen and bog	18	0.419	0.060-1.943
Wild Rice River sedge meadow	1	0.664	—
Lake Itasca			
Wild rice bed	4	0.493	0.127-0.883
Shoreline fen	2	0.165	0.158-0.171

the mosses *Sphagnum angustifolium, S. magellanicum, S. rubellum, S. fuscum, Aulacomnium palustre, Calliergon stramineum* and *Ptilium crista-castrensis*. This location is more fully described by Joyal[16]. The Zerkel sites ranged in *p*H from circumneutral in the pond and the outer part of the floating sedge mat (*p*H 6.1–7.3) to distinctly acid in the ombrotrophic area of black spruce and *Sphagnum* (*p*H 4.1–4.4). Conductivities ranged from 29 to 98 $\mu S\ cm^{-1}$ in various parts of the pond and floating mat, and from 43 to 108 $\mu S\ cm^{-1}$ in the zone of leatherleaf shrubs In the spruce stand, we have one measurement of 60 $\mu S\ cm^{-1}$.

For comparison with other wetland habitats of the region, we measured the CH_4 flux in the Wild Rice River sedge meadow, located ~5 km west of Zerkel, and dominated by *Carex lacustris* and *Calamagrostis canadensis*, and in a stand of wild rice (*Zizania aquatica*) and shoreline fen adjacent to Lake Itasca, Minnesota (47°15′ N, 95°10′ W), where the *p*H ranged from 6.9 to 7.5. The combined set of sites studied are representative of major types of wetlands found in boreal North American ecosystems.

Our results are summarized in Table 1. Note that average CH_4 efflux rates are much the same across a wide range of peatland sites, from circumneutral lake edges and marginal sedge fens through increasingly acid sedge/*Sphagnum* and leatherleaf/*Sphagnum* communities to an ombrotrophic bog community of black spruce and *Sphagnum* This is particularly interesting because laboratory studies using Minnesota peats indicted that $pH = 6$ is optimal for CH_4 production[17]. This difference between laboratory and field observations may well be explained by all variables except *p*H being held constant in the laboratory. At two locations with significantly lower CH_4 flux (Marcell WS-2 and WS-3) our qualitative field observations suggest that differences in peatland hydrology may be important in controlling CH_4 production. The Marcell fen WS-3, which had by far the lowest average daily CH_4 flux, 0.004 $g\ m^{-2}\ day^{-1}$, was the only site with visible water flow in surface peat derived from active groundwater input Thus, we hypothesize that relatively stagnant conditions were present at the other sites studied (conditions at WS-2 were intermediate) which favoured higher rates of methanogenesis. Methane fluxes from the sedge meadow, wild rice, and shoreline fen were similar to rates measured in the bogs.

The distribution of all CH_4 flux measurements made in Minnesota peatlands (Fig. 1) indicates that emission rates ranged over three orders of magnitude. Approximately half of our CH_4 measurements fell within the limited range of 0.1–0.4 $g\ CH_4\ m^{-2}\ day^{-1}$. The logarithmic nature of the frequency distribution of flux rates is of considerable interest. We speculate that the lowest values represent a combination of low decay rates and largely molecular diffusion from the bog surface, whereas the high values, above ~0.4 $g\ CH_4\ m^{-2}\ day^{-1}$, represent scattered 'hotspots' of decaying, recently dead roots or small animals and the possible buildup of methane bubbles.

The only comparable data of which we are aware are from an ombrotrophic *Sphagnum* bog in subarctic northern Sweden[18] where CH_4 emissions ranged from 0.0003 to 0.058 $g\ CH_4\ m^{-2}\ day^{-1}$, a minerotrophic peatland in Sweden[18] that emitted 0.054–0.95 $g\ CH_4\ m^{-2}\ day^{-1}$, and an acid *Sphagnum* bog in the Pennine mountains of England[19] with a range of 0.004–0.03 $g\ CH_4\ m^{-2}\ day^{-1}$ The generally higher emission rates from Minnesota peatlands are probably due, in part at least, to higher soil temperatures that ranged from 14 to 20 °C at 6 cm, as compared with 8 to 16 °C in Sweden and ~11 °C in the British bog[20] during late summer.

Comparison of our flux data with data on other biogenic CH_4 sources indicates that northern wetlands should be considered a potentially significant source of global tropospheric CH_4. For example, our Minnesota flux data are similar to the average emissions of 0.25 $g\ CH_4\ m^{-2}\ day^{-1}$ from California rice paddies[21] and 0.1 $g\ CH_4\ m^{-2}\ day^{-1}$ from rice paddies in Spain[22], and higher than emissions of 0.01–0.09 $g\ CH_4\ m^{-2}\ day^{-1}$ from undisturbed freshwater cypress swamps[23] Two additional factors that determine the global significance of biogenic sources

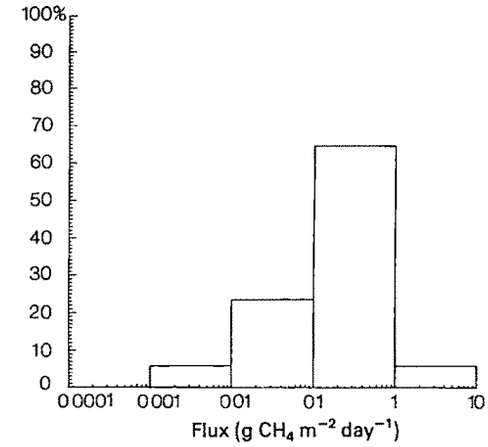

Fig. 1 Histogram of CH_4 flux data from Minnesota peatlands. There were 51 observations which gave a mean flux of 0 337 ± 0 076 $g\ CH_4\ m^{-2}\ day^{-1}$ and a median of 0 173.

of CH_4 are the geographical extent of the source and the duration of emissions. The surface area of boreal and Arctic peatlands and wetlands is not well known. Recently published estimates of these source areas[24] are: boreal bogs and peatland = $1.2 \times 10^6\ km^2$, tundra wet sedge = $1.0 \times 10^6\ km^2$, and tundra tussock = $0.9 \times 10^6\ km^2$. The area of other potentially significant source regions such as wet rice agriculture and Amazonian floodplain are ~$1.1 \times 10^6\ km^2$ and $0.06 \times 10^6\ km^2$, respectively. All of these areas produce CH_4 for 3–6 months a year, depending on climatic and cultivation cycles. We hypothesize that the combination of relatively high emission rates and large areal extent should rank northern peatlands high as a natural source for global atmospheric CH_4. Flux measurements from the great peatlands of Canada and the Soviet Union are needed to test our hypothesis.

Habitats suitable for peat development are largely a result of the most recent glacial period. Extensive peat accumulation began in Minnesota mostly between 3,000 and 4,000 years ago (ref. 25 and E.G., unpublished data). Major peatlands across Canada from British Columbia to the Atlantic Provinces exhibit, as expected, much less synchroneity in 35 basal dates compiled from a variety of sources (E.G., unpublished data). These dates range from 1,600 to 11,200 yr BP, and average 6,500 yr BP. Could the development of boreal peatlands, and their spread by swamping of large areas of surrounding uplands, contribute sufficient additional CH_4 flux to result in a long-term increase in global atmospheric CH_4?

We thank E. S. Verry for assistance at the Marcell Experimental Forest, Shirley Grice for assistance with field measurements, and J. A. Janssens for checking and identifying *Sphagnum* species. This research was supported by the NASA Biospheric Research Program and the NSF Ecosystem Studies Program. P.A.F. was a NRC Resident Research Associate at the NASA Langley Research Center.

A lattice statistics model for the age distribution of air bubbles in polar ice

I. G. Enting

CSIRO, Division of Atmospheric Research, Private Bag 1, Mordialloc, Victoria, Australia 3195

Measurements of CO_2 in bubbles in polar ice have been used to establish a pre-industrial concentration[1-4]. Similar measurements have been made for other atmospheric constituents[5,6]. However, in order to use ice-core measurements to determine the increase in CO_2 over the last 200 years, it is necessary to consider the time delay between the deposition of the original snow and the bubble trapping and also the distribution of trapping times over several decades[7]. The percolation model from lattice statistics describes the static geometrical aspects of trapping and reproduces various aspects of recent observations. The observations of large seasonal fluctuations in trapped bubble volume reflect the enhanced susceptibility to perturbations near the percolation transition. The critical exponent of the percolation probability largely determines the stability of the deconvolution of observed concentrations, indicating that the bubble deconvolution problem is less poorly posed than typical geochemical source deduction problems.

In order to represent the relation between atmospheric concentrations and bubble concentrations, a negative time variable z (in years) is introduced. The variable z increases with depth and has its origin at the present (that is, the time at which the ice core was extracted). The atmospheric concentration of CO_2 (or other tracer of interest) z years ago is denoted $c(z)$. The mean concentration in bubbles in a layer deposited z years ago is denoted $q(z)$. The trapping function $R(z)$ gives the amount of air in a layer that was trapped z years after the layer was deposited and is expressed as a proportion of the total amount of gas that will be trapped. Thus $R(z)$ is normalized to

$$\int_0^\infty R(z)\,\mathrm{d}z = 1 \qquad (1)$$

From the definition of $R(z)$, it follows that the relation between q and c is

$$q(z) = \int_0^z R(z-z')c(z')\,\mathrm{d}z' \qquad (2)$$

The static geometric aspects of bubble-trapping can be naturally modelled by using the percolation model of lattice statistics[8-10]. This model is usually studied for regular lattices and considers connected clusters in a lattice where elementary steps in possible connecting pathways are broken in a random uncorrelated manner. A key quantity in the theory is the percolation probability, $P(p)$, which gives the probability that a given lattice element is part of an infinite cluster of connected elements with p being the probability that an individual step in the lattice is broken. The main results of percolation theory are that there is a critical probability p_c above which $P(p)$ is zero and that $P(p)$ behaves as $(p_c-p)^\beta$ for $p \to p_c^-$. It was pointed out by Kasteleyn and Fortuin[11] that the percolation model is a limiting case of the Potts models[12], a family of models used in statistical mechanics to describe a range of continuous phase transitions. The property that distinguishes such transitions and makes them difficult to analyse is that the transition behaviour is influenced by fluctuations on all possible length scales.

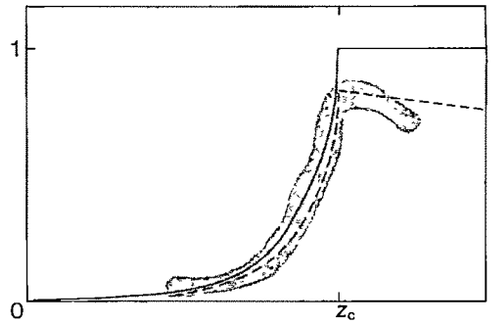

Fig. 1 A schematic representation of the cumulative trapping function as predicted by percolation theory (solid curve). The age distribution function is the derivative of this curve. The dashed curve shows the effect of a correction applied to convert the fraction trapped into bubble volume. Shading shows the range of observed volumes[7], with the horizontal and vertical scales chosen to give agreement at the 50% and 100% points.

Having established the connection with statistical mechanics, the techniques of the renormalization group[13] in statistical mechanics can be used to justify earlier conjectures of universality in percolation models. This implies that the exponent β depends on the dimensionality of the system but will be the same for all three-dimensional lattices and for amorphous three-dimensional systems such as that involved in firn closure. (The exponents will also be the same for the so-called 'site' and 'bond' problems[8-10], which is why the neutral terms 'step' and 'element' were used above.)

As a layered system the firn should be regarded as being two-dimensional. However, it is only very near p_c that the correlations become long enough to detect the essential two-dimensional nature so that the β for two-dimensional systems should apply. Further away from p_c the shorter-range correlations see an essentially three-dimensional structure. In the firn system the crossover[14] from $\beta_{2D} = 5/36$ (conjectured[15,16]) to $\beta_{3D} \cong 0.454$ (series estimate[17]) should be so close to p_c as to be undetectable. The remaining discussion will assume a purely three-dimensional description.

To model firn closure using percolation, the elements in the infinite cluster are those that are still connected to the atmosphere. If we assume that the channel closure probability, p, increases smoothly with age z, then we can consider the percolation probability as a function of z without changing the critical exponents and there will be a critical delay time, z_c, at which point all gas has been trapped. $P(z)$ represents the proportion of gas-containing elements *not* trapped at time z after deposition so $1-P(z)$ represents the cumulative proportion trapped. The incremental trapping function $R(z)$ is thus

$$R(z) = -\frac{\partial P(z)}{\partial z} \sim (z_c - z)^{\beta-1} \quad \text{as } z \to z_c^- \qquad (3)$$

Schwander and Stauffer[7] measured the bubble volume of trapped bubbles as a function of depth. In the percolation model the proportion trapped is $1-P$, which is plotted schematically as the solid line in Fig. 1. To convert this to bubble volume, a depth-dependent factor must be included to allow for the fact that the bubbles are subject to compression once trapped. The result is shown schematically as the dashed line in Fig. 1; the range of values observed by Schwander and Stauffer is shown by the shaded region. As the general theoretical results do not determine the specific relation between the measured ice density and the bond closure, both the horizontal and vertical scales on Fig. 1 have been linearly related to those used by Schwander and Stauffer[7] so as to match the points of 50% and 100% trapping. The percolation model adequately describes the geometrical aspects of bubble trapping, but the assumption of proportionality between z and the compression factor is inadequate.

Both the percolation model and the measurements by Schwander and Stauffer[7] determine the time of bubble trapping relative to the time of snow deposition and do not directly determine the age of the air that is trapped. However, measurements of ^{39}Ar indicate that air in the 'open' volume is well mixed throughout the firn[18], so that the trapping time distribution should be close to the age distribution.

For use in solving equation (1), the percolation model will require an empirical calibration using data such as that plotted by Schwander and Stauffer[7] even if only to determine the amplitude of the singularity. Direct theoretical calculation of $P(z)$ seems impractical mathematically since even highly structured lattice percolation problems do not have closed form solutions. Even an approximate calculation of $P(z)$ would require more detail of the firn structure than is readily available.

Given the singular nature of $R(z)$, it is of interest to note that the ice-core deconvolution problem is less poorly posed than many typical geochemical inversion problems. Equation (1) becomes

$$q(z) \sim \int_{z-z_c}^{z} (z_c - z + z')^{\beta-1} c(z')\, dz', \text{ for } z > z_c \qquad (4a)$$

or putting $t = z_c - z$, $t' = -z'$

$$q(z_c - t) \propto \int_{t-z_c}^{t} (t - t')^{\beta-1} c(-t)\, dt' \qquad (4b)$$

Apart from the variable lower limit (which has little influence on the integral) this is proportional to the expression given by Ross[19] for defining a β-fold integration of $c(-t)$ for non-integer β. The inverse operation of obtaining c from q corresponds to the operation denoted by

$$c(t) \propto \frac{d^{\beta}}{dt^{\beta}} q(t) \qquad (5)$$

Anderssen and de Hoog[20] have characterized the numerical difficulty of unstable inverse problems as being given by the equivalent order of differentiation when this is applicable. Most source deduction problems in geochemistry are essentially equivalent in difficulty to a single numerical differentiation since observed concentrations represent the integrated effects of sources. If the percolation model is valid, the deconvolution of bubble concentrations in ice cores is formally equivalent to about a 0.454th-order differentiation and so is less poorly posed than typical source deduction problems in geochemistry. Thus the resolution which can be achieved for the reconstruction of c should be somewhat better than the time period over which the firn closes.

Since submission of this manuscript we have learnt that the bubble trapping problem has also been considered in terms of the percolation model by B. Stauffer, J. Schwander and H. Oeschger (unpublished data). They performed simulations using a regular lattice approximation and concentrated on determining the critical point rather than discussing the critical exponent.

Cherts of the Doushantuo Formation in the Yangtze Gorges, South China, contain a superbly preserved heterogeneous assemblage of bacteria, cyanobacteria, planktonic algae, submillimetre-sized burrows and problematica. The microbiota has a bearing on defining the Precambrian–Cambrian boundary. *Baltisphaeridium* and associated spinose microfossils in the chert suggest an early Cambrian age whereas other acritarchs, vendotaenids and pretrilobite small shelly fossils from the conformably overlying the Dengying Formation, indicate a late Proterozoic age for the Doushantuo. This mixed benthic–planktonic assemblage preserved in silicified, laminated, microbial mat-like fabrics, provides a unique sample of diverse microbiotic elements existing at the dawn of the Phanerozoic and records the earliest evidence of meiofauna.

The fossil record of the latest Proterozoic is best known from Ediacaran and allied soft-bodied animals[1,2], acritarchs[3] and stromatolites[4]. This record, though meagre, is fascinating, for it was during this interval that animals originated and began to diversify[5]. Much of our understanding of pre-700-Myr-old palaeobiology has been based on interpreting fossils preserved in chert[6]; unfortunately such occurrences are not well known from post-700-Myr old deposits

The Doushantuo Formation in the Yangzte Gorges, China, conventionally viewed as late Proterozoic[7,8], contains cherts with well-preserved, abundant and diverse microfossils such as coccoid and filamentous cyanobacteria, bacteria, large spiny organic-walled microfossils, problematic tubular microfossils, other problematica and submillimetre-sized backfilled burrows. In addition to a benthic mat biota, the cherts preserve elements of the phytoplankton that lived in the overlying water column.

The Doushantuo Formation is a dark brown to grey-black dolomite with chert, interbedded with shale. It unconformably overlies tillite of the Nantuo Formation and is conformably overlain by dolomite and limestone of the Dengying Formation[9] (Figs 1, 2).

The Yangtze Gorges region contains the type section for the Chinese Sinian System[10] (composed, in ascending order, of the

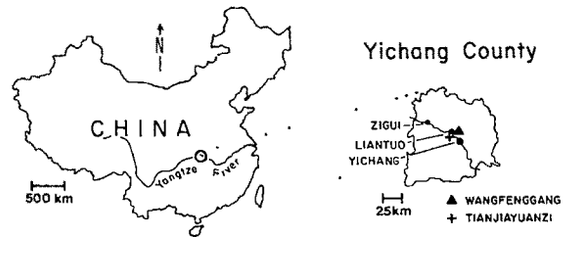

Fig. 1 Index maps showing location of measured sections.

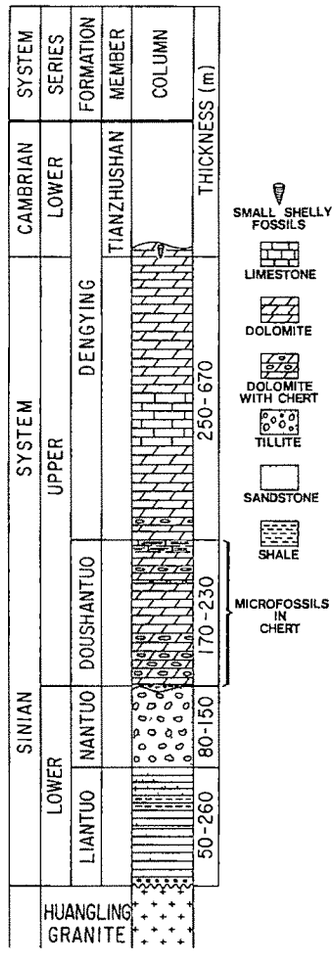

Fig. 2 Generalized stratigraphical column of Sinian System in the Yangtze Gorges, Yichang County, Hubei, China.

Liantuo, Nantuo, Doushantuo and Dengying formations). It would be a potential candidate for any global stratotype section that may be established for a new geological system to embrace the pre-shelly fossil record during which metazoans appeared[11]. Here the Sinian is a thick succession with such lithological and palaeontological curiosities as tillite, phosporite, acritarchs, vendotaenid algae, stromatolites, oncolites, microfossiliferous chert, putative Ediacaran-type metazoans, sponge-like spicules, trace fossils and is conformably overlain by the small shelly fossil-bearing Tianzhushan member (upper Dengying Formation), regarded as signalling the base of the Cambrian[9,12].

Within this stratigraphical framework, the Doushantuo is usually taken to be Late Sinian (Vendian or Ediacarian), probably <700 Myr-old. Although their reliability may be questioned, Rb-Sr whole rock isochron ages from the top of the formation yield 700±5 and 691±29 Myr (ref. 13). Other potential radiometric age constraints include an ion-probe U-Pb age of 740±16 Myr on zircons in tuff from the Lower Sinian Liantuo Formation[13], and ages of 806±6 Myr (Rb-Sr isochron) and 823±7 Myr (K-Ar on biotite) from the crystalline basement underlying the Liantuo[13]. Shale from the upper part of the Tianzhushan member (Dengying Formation) has an inferred isotopic age of 610±10 Myr based on whole rock Rb-Sr isochron analyses[14]. Palaeontologically, acritarchs from acid residues of Doushantuo clastic rocks have been interpreted to indicate a late Proterozoic age (<700 Myr)[7,15]. The overlying Dengying Formation's palaeontology (vendotaenids from the lower part[9]; pre-Cambrian acritarchs from shale[7,9], and small shelly fossils of Meichucunian or Tommotian character at the top[7]) also indicates a pre-Cambrian age for the Doushantuo. Following guidelines set forth by the International Union of Geological Sciences/International Geological Correlation Program Project 29 Working Group on the Precambrian-Cambrian Boundary[16], the small shelly fossils appearing in the Tianzhushan member (Dengying Formation; Fig. 2) would define the base of the Cambrian. Hence, until now, the overall palaeontology, stratigraphy, isotope age data and correlations with other areas suggested a late Proterozoic age for the Doushantuo.

Previously reported fossils from the Doushantuo Formation include stromatolites[17], acritarchs[15] and chitinozoans[17]. Cyanobacteria[18-20] and spiny microfossils[21,22] have been described from chert and sponge-like spicules from dolomite[17]. No megascopic algal, metazoan trace or body fossils have yet been found in the Doushantuo.

The microfossils that we describe here were detected in petrographic thin sections of chert nodules in dolomite from two measured sections of the Doushantuo Formation; one ~150 m east of Wangfenggang Village, the other ~700 m south-southeast of Tianjiayuanzi Village, Yichang County, Hubei, China (Fig. 1). Of the coccoidal microfossils detected, solitary specimens are rare; the more abundant pluricellular varieties are represented by such Proterozoic taxa as *Myxococcoides*, *Palaeoanacystis* and *Tetraphycus*. Among the new taxa present are a *Merismopedia*-like pluricellular form with tightly packed cubic cells and an aggregate of small <1-μm diameter cells that might represent fossilized bacteria. In general, most of the coccoidal morphs resemble cyanobacteria; however, although diverse, the coccoids are only moderately abundant when compared with filaments and large spinose morphs.

The benthic component of the microbiota is dominated by filamentous fossils that resemble cyanobacteria. Bundles, 50–400 μm across, of filaments, 5–45 μm in diameter, are common (Fig. 3*a*) and many superficially resemble the extant multitrichomous oscillatoriacean *Microcoleus* Numerous single filaments, ranging from <1 to as much as 100 μm in diameter, and representing several taxa, occur as solitary strands and in matlike arrangements. Rare examples of an *Obruchevella*-like fossil have been found. Most filaments resemble the empty sheaths of cyanobacteria although others may be bacteria and algae. Preservation at times is so good that a trichome can be found preserved within its sheath (Fig. 3*d*) No heterocystous or branched filaments have been detected.

Cyanobacteria-like fossil diversity is high; >20 species are present. These microfossils occur in rudimentary, stratiform stromatolite-like microstructures not too unlike those seen in Proterozoic microfossiliferous stromatolites[23]. In some instances, this rudimentary lamination is disrupted in a manner suggesting churning of the sediment by organisms that did not leave clear, well-defined burrows.

Planktonic microfossils include a variety of morphotypes. Among the most conspicuous and abundant plankters found in thin section are diverse spinose vesicles, ranging from 30 to 1,200 μm across. Important among these are the spiny acritarchs resembling *Baltisphaeridium* (Fig. 3*b*) hitherto known only from early Cambrian and younger rocks[24,25].

The Doushantuo also contains abundant and diverse, morphologically-complex microscopic fossils of uncertain systematic position. First, there are robust, multilayered and partitioned tubes (Fig. 3*c*). These fossils, 40–100 μm in diameter, occur in variable abundance in numerous thin sections from several sites. At first glance, these tubes resemble large, lamellated, oscillatoriacean cyanobacterial sheaths. However, oscillatoriaceans and other filamentous cyanobacteria, bacteria, algae, and fungi are not known to possess this type of architecture. Superficially they resemble miniaturized coelomates; however, the small size and apparent partitioning of the innermost tube (which would be equivalent to the gut) make this affinity unlikely. This morph might represent an evolutionary novelty in the prokaryotic or eukaryotic line for which there are no modern analogues.

Also, large, 400–900-μm wide and 750–1,500-μm long, morphologically complex, brown coloured vesicles (Fig. 3*f*) have been found in many thin sections from several sites. The fossils are characterized by a tripartate organization consisting of: (1)

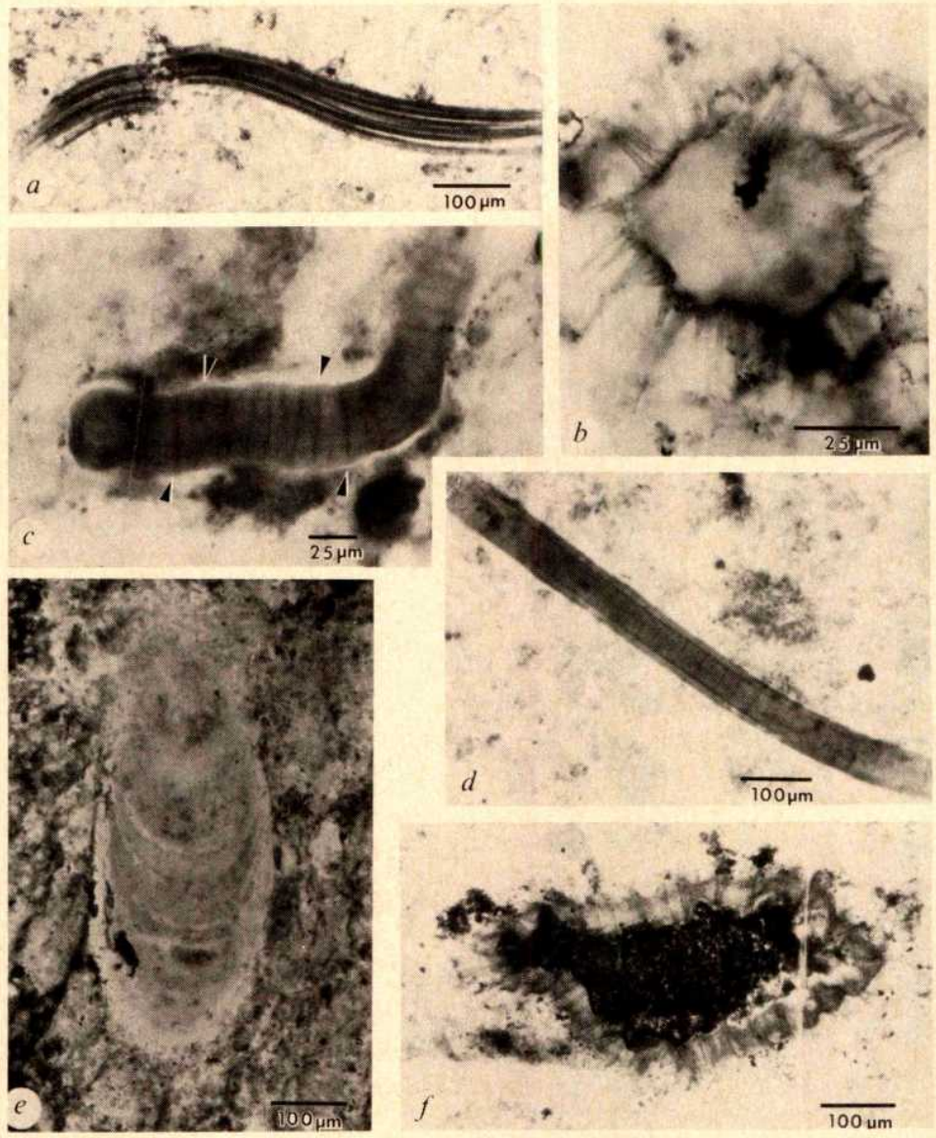

Fig. 3 Microfossils from the Doushantuo Formation. All photomicrographs are from petrographic thin sections housed in the Preston Cloud Research Laboratory. *a*, Bundle of filaments showing possible multitrichomous habit. Sheath is not evident. *b*, *Baltisphaeridium* spiny microfossil; note the closed, tapered ends of the spines. *c*, Partitioned, concentrically-layered tube. Partitions, indicated by arrows, cut the layered cylinder. It is uncertain even to what kingdom this fossil belongs. *d*, Cyanobacterium with trichome preserved within lamellated sheath. The outer sheath is not partitioned and the inner trichome is not layered. *e*, Backfilled burrow. This burrow and others like it (preserved in chert), pre-date previously known bona fide burrows from the Sinian of China. *f*, Complexly organized protistan showing outer layered organic mantle with tube clusters, boundary layer, and interior with particulate contents.

the vesicle interior that typically contains amorphous black particulate organic and pyritic matter and occasionally folded membrane-like material; (2) a well-defined boundary layer or wall that separates an external organic covering from the vesicle interior; and (3) an outer organic covering or mantle that is occasionally layered, as seen in Fig. 3*f*. This organic covering contains clusters of from 3 to 8 small, hollow tubes, each 1–3 μm in diameter. The tubes have closed, tapered ends. Where attached to the boundary, the tubes open to the vesicle's interior. The tubes, wall structure, interior and overall organization of these microfossils are unlike that of previously described spinose acritarchs, although some similarities exist with the Proterozoic morph *Trachyhystrichosphaera*[26]. Superficially they also resemble certain protozoan sporocysts like those of gregarines. The size and complexity of these fossils indicate some kind of eukaryote, probably a protistan. Again the possibility exists that these fossils have no modern analogues.

Structures resembling backfilled burrows, 150–250 μm across (Fig. 3*e*), are known from two collecting sites. Longitudinal and cross-sections of these burrows are found oriented both parallel to, and oblique to, lamination in chert nodules. Although rare (four examples known) and in the case of Fig. 3*e* composed of chalcedony, they probably represent some worm-like meiofaunal animal that peristaltically moved through sediment. These structures cannot be interpreted as laminated constructional features like microstromatolites for the layering is concave down and disrupts chert matrix laminae. The presence of such submillimetre-sized, backfilled burrows in the Doushantuo suggests meiofaunal activity and, if the age of the Doushantuo proves to be late Proterozoic, make them among the oldest burrows known.

Clearly, the discovery of *Baltisphaeridium* and related spinose vesicles in Doushantuo cherts raises questions, not only about the age of the Doushantuo, but also concerning criteria and reliability of criteria used to define the Precambrian–Cambrian boundary.

This precise age controversy aside, the exceptional preservation of the abundant and diverse prokaryotic and eukaryotic fossils in the Doushantuo cherts provide a unique microscopic window on a time during the early stages of animal evolution and the waning of stromatolite-building microbial mat communities[27]. These new data must be considered when defining one of the major boundaries of the geological time scale. The robust nature of many of the cyanobacteria (large size, thick sheaths) as well as some of the problematic morphs may have been an attempt by mat-forming organisms to cope with newly evolved 'meiofaunal' and macrofaunal benthic eukaryotic heterotrophs that ultimately overwhelmed the stromatolite-building biocenoses: an extraordinarily successful biocenose that had flourished for hundreds of millions of years.

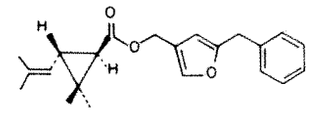
Energy transfer at the surface of clays and protection of pesticides from photodegradation

Leon Margulies*§, Harel Rozen* & Ephraim Cohen†

* Seagram Centre for Soil and Water Sciences, and
† Department of Entomology, Faculty of Agriculture,
The Hebrew University of Jerusalem, PO Box 12,
Rehovot 76-100, Israel

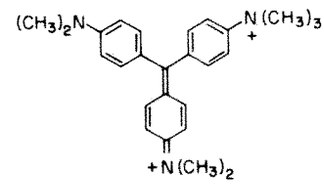
Certain potential pesticides are of limited use because of their sensitivity to sunlight. Previous attempts to overcome this limitation have been unsatisfactory because of impairment of insecticidal efficiency or unwanted toxic properties. The photosensitivity results from the balance between the processes, such as energy transfer and chemical reaction, by which photoexcited molecules can release excess energy and return to the ground state. The efficiency of the various energy transfer mechanisms[1-5] depends, in some cases, on the specific spectroscopic characteristics of donor and acceptor molecules, the distance between them and their relative orientations. We present here an approach aimed at protecting compounds of agricultural interest (for example, pesticides) by exploiting the unique surface properties of certain clays in order to build systems in which fast energy transfer occurs before photodegradation starts.

Clays, such as montmorillonite, exhibit outstanding adsorption properties due to their high specific surface areas and high cation-exchange capacities[6]. As organic molecules adsorbed on the clay surface are oriented[7], their intermolecular distances and orientations might fulfil the requirements for an efficient energy transfer process. Measurements of energy transfer on clay surfaces have been described for certain fluorescent cations[8-10]. However, occurrence of such processes between adsorbed non-fluorescent photolabile organic molecules has not been reported.



A suitable target for study of photostabilization is the synthetic non-halogenated pyrethroid bioresmethrin (BR) (5-benzyl-3-furylmethyl) (1R)-*trans*-chrysanthemate), a powerful contact insecticide effective against a wide range of insect pests and one of the safest pesticides (its acute oral LD_{50} (50% lethal dose) for rats is 8 g per kg). Despite these advantages, bioresmethrin is not used in agriculture owing to its rapid photodecomposition.

§ To whom correspondence should be addressed.



It was found that chemical modification of the pyrethroid structure leads, in some cases, to more stable pesticides[11-16]. Attempts have been made to stabilize the photolabile pyrethroids using various additives (antioxidants and UV-screeners)[17-22]. Recently, the photostabilization of cyphenothrin by dinitroanilines at certain relative concentration ratios has been attributed to possible exciplex or charge transfer quenching[22].

We have achieved stabilization of BR by adsorbing it on montmorillonite (Clay) together with the divalent cation methyl green (MG). Figure 1 shows the results of a typical bioassay using adults of the flour beetle *Tribolium castaneum*. Control samples of free BR exposed to sunlight completely lost their biological activity in <2 h, whereas samples prepared according to our method were still active after several days of exposure to sunlight. BR adsorbed in a complex with 0.2 mmol of MG per g clay was photochemically more stable than BR in a complex with a higher level of dye (0.4 mmol g^{-1}). This indicates that the stabilization effect is due to specific interactions between the two compounds at the surface of the clay rather than to merely a UV-screening effect.

Some details of these interactions at the molecular level can be obtained using Fourier transform IR (FTIR) spectroscopy (Fig. 2). A comparison of spectrum *a* (free BR) with spectrum *b* (BR adsorbed on clay) reveals that the stretching frequency of the C=O bond shifts from 1,722 to 1,709 cm^{-1} on adsorption.

BR

MG

The position of this band in spectrum *c* (BR adsorbed in the presence of MG) clearly shows that the BR molecules in the Clay-MG-BR complex are adsorbed in a similar manner as in the case of Clay-BR. Minor changes in the strong absorption bands of MG at 1,568 and 1,371 cm^{-1} are also induced by the co-adsorption of BR. These changes, although difficult to observe in the measured spectra (Fig. 2*d*, *e*), are evident in the difference spectrum (Fig. 2*c*). In addition, co-adsorption of MG and BR induces broadening of the 1,497 cm^{-1} peak of BR. The fact that vibrational frequencies of one organic molecule are shifted due to the co-adsorption of another one (as detected by the differential FTIR technique) indicates that short-distance intermolecular interactions exist between the molecules of these substances on the clay surface. A change in concentration of the adsorbed molecules results in a modification of the intermolecular distances and/or relative orientations in a manner which evidently affects the efficiency of the photostabilization effect (Fig. 1).

The method we propose for protecting pesticides from photodegradation thus consists of adsorbing the photolabile agrochemical to the surface of a clay to which another organic chromophore has been attached. This second organic chromophore may be selected according to its spectroscopic, geometric and charge characteristics, depending on the type of clay to be used and the pesticide to be protected. If the clay is a smectite, such as montmorillonite, with a negatively charged surface, a cationic protective compound may be used. As a result of its adsorption to the clay, the charge at the adsorption site is neutralized and the surface might become hydrophobic (depending on the size of the organic cation). If a non-ionic presticide molecule is added to this system, it will be adsorbed at these hydrophobic sites or, alternatively, it might be attached

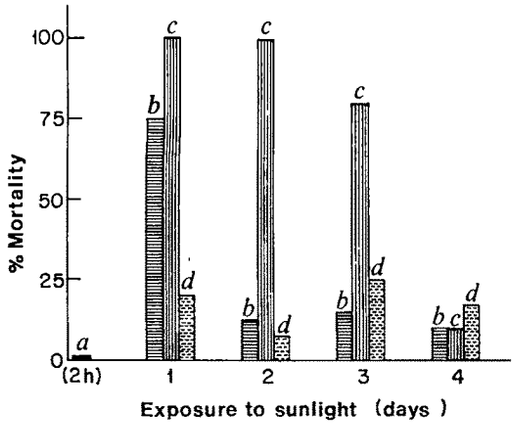


Fig. 1 Bioassay to evaluate protection of bioresmethrin from photodegradation. *a*, Unprotected bioresmethrin, *b–d*, montmorillonite(Clay)-methyl green(MG)-bioresmethrin(BR) complexes with different MG loading. The concentration of BR in all three cases was 0.2 mmol per g clay. Concentrations of MG, relative to clay, were: *b*, 0.1 mmol g^{-1}; *c*, 0.2 mmol g^{-1}; *d*, 0.4 mmol g^{-1}. Clay-MG-BR complexes were prepared as follows: aliquots of a 10^{-3} M aqueous solution of MG were added dropwise to a 0.5% aqueous suspension of Na-montmorillonite (SWy-1 from the Clay Minerals Society repository). After separation by centrifugation at 16,000*g*, the precipitate was washed three times with distilled water, freeze-dried and ground to <50 μm. The appropriate volume of a 10^{-2} M solution of BR in hexane was added to this powder and the solvent was evaporated under reduced pressure. For bioassays, 10 mg of the complex was deposited on the bottom of Petri dishes (5-cm diameter) and exposed to sunlight for various intervals of time; 2-week-old *Tribolium castaneum* (CSbb strain) adults were used. After irradiation, 20 insects were transferred from stock cultures to the Petri dishes and the percentage mortality was recorded. Irradiated controls of Clay-BR complexes (BR adsorbed to montmorillonite in the absence of MG) gave 0% mortality after 4 h of exposure to sunlight. In all cases controls protected from light gave 100% mortality.

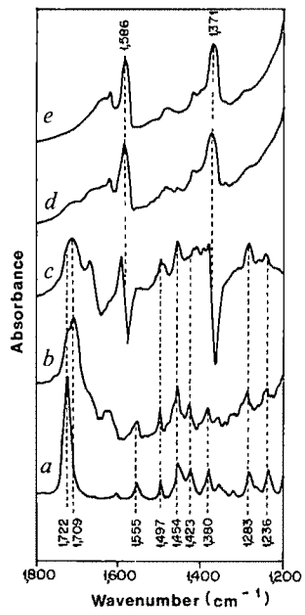

Fig. 2 Fourier transform IR absorption spectra of. *a*, bioresmethrin (BR); *b*, BR adsorbed on montmorillonite. The latter spectrum was obtained by subtracting the spectrum of the clay from that of the complex Clay-BR (none of which are shown). *c*, BR adsorbed in the complex Clay-MG-BR, obtained by subtraction of spectra *e* and *d*. 'Negative' peaks just below 1,586 and 1,371 cm^{-1} result from small shifts in the MG transitions at these positions due to co-adsorption of BR. *d*, Clay-MG-BR, with 0.2 mmol of each of MG and BR per g clay; *e*, Clay-MG (0.2 mmol MG per g clay). All spectra were measured in KBr pellets using a Nicolet MX-S FTIR spectrophotometer.

to the clay surface either directly or through interaction with adsorbed inorganic cations and/or interlayer water molecules. The actual mechanism will depend largely on the structure of the pesticide molecule (nature of functional groups) and on the extent of coverage of clay surface by the organic cation. Following photoexcitation of pesticide molecules, an efficient energy transfer between them and neighbouring organic cations might take place at a high rate, thus preventing the photochemical decomposition of the bioactive compound. In such a system, the protective compound is linked to the clay surface by strong coulombic bonds, whereas the pesticide molecules are retained by much weaker bonds and can be easily detached from the surface, as required for insecticidal activity.

We thank B. Kaminski for technical assistance, and A. Banin, S. Nir and P. Barak for critical reviews of the manuscript. Financial support by the Peter Haas and E. D. Bergman Foundations is acknowledged.

Patterns of family extinction depend on definition and geological timescale

Antoni Hoffman

Lamont-Doherty Geological Observatory, Columbia University, Palisades, New York 10964, USA

The recent claim[1] of an approximate 26-Myr periodicity in the pattern of mass species extinction over the past 250 Myr has already stimulated much astrophysical speculation and debate on causal mechanisms[2–13]. However, as shown here, the evidence for that claim is strongly contingent on arbitrary decisions concerning the absolute dating of stratigraphical boundaries[14], the culling of the database and the definition of what is mass extinction as opposed to background extinction. This evidence becomes insufficient under other plausible geological timescales and other acceptable definitions of mass extinction. Analysis of the non-culled database shows that the reliability of identification of mass extinctions and their timing is at present extremely limited. It also suggests that the apparent periodicity of mass extinctions results from stochastic processes.

The database for recent studies on global patterns of diversity and extinction usually consists of Sepkoski's compendium of stratigraphical ranges of all marine animal families in the Phanerozoic[15]. The stratigraphical resolution is to the level of universally recognizable units called stages (some of them are indeed stages, others are clusters of stages or even series). This compendium is taken at its face value, although the earlier

Asterisks denote major maxima, circles denote minor, perhaps insignificant maxima. *A*, Probabilistic rate of extinction per stage, culled data set, maxima defined as local peaks, *B*, number of family extinctions per stage, complete data set, maxima defined as local peaks; *C*, probabilistic rate of extinction per stage, complete data set, maxima defined as local peaks; *D*, probabilistic rate of extinction per stage, complete data set, maxima defined as points more than one standard deviation above the regression line (the same maxima obtain for the number of family extinctions per stage); *E*, number of family extinctions per Myr, complete data set, maxima defined as local peaks (H, timescale given by Harland *et al.*[33]; H1, H2, H3, timescales randomized within the limits of analytical error of absolute dates given by Harland *et al.*; O, timescale given by Odin[32]; O1, O2, O3, timescales randomized within the limits of analytical error of absolute dates given by Odin); *F*, probabilistic rate of extinction per Myr, complete data set, maxima defined as local peaks (timescales as for *E*).

demonstration by Raup[16,17] and others[18–20] that these kinds of data are strongly biased has never been refuted. The data are at the family level of taxonomic hierarchy, and the resultant patterns may not agree with the patterns at the species level[21]. For instance, the Toarcian maximum of species extinction[22–24] is unrecognizable at the family level, whereas the late Eocene maximum of family extinction does not show up at the species level[25–28]. Therefore, the following analysis is, for the sake of consistency, confined to the family level.

The database analysed for periodicity in mass extinction[1] is only a subset of Sepkoski's compendium. This subset is defined by exclusion of extant families and families with imprecise or questionable stratigraphical ranges. The time frame is the latest Permian (Dzhulfian) to middle Miocene. The data culling was intended to remove the noise and the pull of the Recent[16], but it results in data reliability being much lower in the Cenozoic than in the Mesozoic. For instance, the middle Miocene demise of 5 families becomes a possible mass extinction and the late Eocene demise of 10 families is a very pronounced event, whereas 19 families going extinct in the Campanian represents a period of low extinction and the late Permian extinction involves hundreds of families. Clearly, the alleged mass extinction events are incompatible with each other. Furthermore, the removal of extant families causes some extinction peaks to shift; probability of family extinction is higher in the late Eocene than in the middle Eocene only because the family number, that is, denominator, is artificially decreased in the former. The data culling also results in arbitrariness, for there is no criterion to determine which stratigraphical ranges are unquestionable. This must be an arbitrary decision because each range may be extended in either direction by new discoveries (probabilistic methods[29,30] are useless because neither family encounter frequency nor sequence in independent samples can be analysed). The time frame of Raup and Sepkoski's analysis arbitrarily cuts off the Guadelupian (extinction rate and probability higher than in the Dzhulfian) as well as the late Miocene (five family extinctions, as in the middle Miocene) and Pliocene (seven family extinctions). Had the Guadelupian and Pliocene, rather than Dzhulfian and middle Miocene, been accepted as mass extinctions, the 26-Myr periodicity would have to be rejected.

Hence, the following analysis is based on all Guadelupian to Recent taxa recorded in Sepkoski's compendium. Family extinctions with stratigraphical resolution to the series or system level are assigned proportionately to the stages, a procedure which accentuates maxima of extinction. Nevertheless, the culled data set analysed by Raup and Sepkoski shows eight maxima with extinction probability exceeding 0.1 (cutoff level for mass extinctions at the family level[2,31]), whereas the complete data set gives only two events of this magnitude (Guadelupian, Maestrichtian) and only four additional events exceeding the 0.05 level (Olenekian, Norian, Tithonian, Cenomanian). This difference clearly shows the impact of data culling by Raup and Sepkoski.

Analysis of the timing of geological or palaeontological events obviously must depend on the geological timescale. There is much uncertainty in absolute dating of stratigraphical boun-

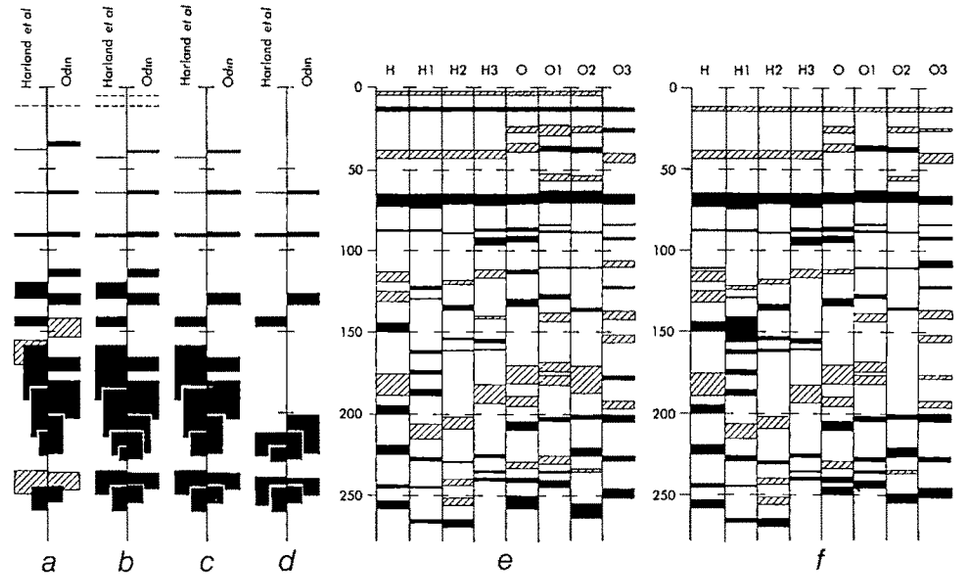

Fig. 1 Time distribution of maxima of family extinction, depending on definition and geological timescale (see Table 1 for explanation and event identification), vertical scale in Myr. Mass extinction events occurred somewhere within time ranges given by the black bars; hatched bars (or dashed lines) denote minor, perhaps insignificant, maxima.

daries. Two recent timescales[32,33] differ by as much as 10–14 Myr for many stratigraphical boundaries in the Mesozoic. This difference might increase to over 20 Myr if the analytical errors of absolute dates, as estimated by the authors of the two scales, run in opposite directions. (The timescale uncertainty is thus not much less than in the post-Cambrian Palaeozoic, where no 26-Myr periodicity in mass extinctions has been discovered[1].) The correlation is only moderate between the two timescales and its statistical significance is largely due to the generally good dating, and hence agreement between the timescales, for the late Cretaceous and Cenozoic. This correlation, however, dramatically decreases for randomized modifications of the timescales, with stage durations determined at random within the limits of analytical error of the absolute dating as given by the authors of the timescales. Such a randomization assumes that, contrary to the timescale of Harland *et al.*[33] accepted by Raup and Sepkoski, stratigraphical stages vary in duration This assumption, however, is strongly corroborated by the evidence from, for instance, late Cretaceous stages ranging from 1 Myr (Coniacian) to 15.5 Myr (Albian)

Analysis of the timing of mass extinctions naturally depends on the choice made from a variety of criteria for distinguishing between mass extinction and background extinction. This is not a trivial matter, for, as noted by Raup *et al.*[34], "it is entirely possible that the initial assumption . . . , that background extinction and mass extinction constitute two discrete populations, may not be correct". Rate or probability of extinction can be taken as extinction metrics. If extinctions are assumed to occur episodically rather than continually, the use of rate or probability per stratigraphical stage is reasonable. This is an *ad hoc* assumption but it may be substantiated by the evidence for catastrophic physical events (for example, extraterrestrial impacts) as the causes of mass extinction and by the absence of correlation between extinction and stage duration[1]. There is, in fact, strong evidence that the terminal Maestrichtian extinction is associated with[35–41], though not necessarily caused by[42–46], a major physical catastrophe, and only disputable evidence for coincidence of the late Eocene extinction peak with a physical catastrophic event[26,47,48]. However, evidence for association of other alleged mass extinctions with major catastrophes is largely absent[46]. On the other hand, the absence of correlation between extinction and stage duration may be caused by the fallacy of equal stage durations; besides, it is irrelevant to individual events. If the assumption that extinctions occur episodically is rejected, extinction rate or probability per Myr should be applied as the appropriate extinction metric, as in the analyses of extinction intensity through geological time[49,50].

Mass extinctions may be defined as peaks of the curve[1]. An arbitrary level of extinction metric may, then, be set to distinguish between true and spurious peaks caused by minor and inevitable fluctuations in background extinction[2,31]. Such a definition is appropriate for extinction metrics normalized for time, although it ignores the possibility of prolonged periods of unusually high extinction. As judged after Sepkoski's data[15], the latter may be the case with (Givetian?–) Frasnian–Famennian, Guadelupian–Dzhulfian and Carnian–Norian–Rhaetian. On the other hand, definition of mass extinctions as peaks of the curve rules out the possibility that two, or even more, consecutive stages were periods of mass extinction. Yet instantaneous mass extinction events may well be separated by one stage only. This may be an alternative interpretation of consistently high extinction in the late Devonian, late Permian and late Triassic if each stage was taken to represent an individual event. Therefore, such a definition is inappropriate for extinction metrics per stratigraphical stage. Instead, all rates or probabilities exceeding a certain arbitrary level can be recognized as mass extinctions. Alternatively, rates or probabilities more than, say, one standard deviation above the regression line over geological time can be identified as mass extinctions. The latter definition takes into account the substantial decrease in extinction intensity through time[49,50].

Table 1 shows the wide array of stages that appear as mass extinctions, depending on definition and timescale. There is some apparent regularity in the pattern of mass extinction events defined as peaks of extinction metrics not normalized for time (Table 1*A–C*), but this may well be pseudoperiodic behaviour of a stochastic system; when the absolute magnitude of alleged mass extinctions is taken into account in addition to their timing, such a model shows a better fit to the empirical pattern[51]. When the absolute magnitude of extinction peaks is disregarded, however, as in Raup and Sepkoski's analysis, such a definition causes the empirical pattern to represent only relative changes in extinction metric over relative geological time. Thus, the conditions for random walk are met. Given a strict random-walk model (0.5 probabilities of both increase and decrease in extinction metric, regardless of what happened at the preceding step), there is 0.25 probability that any particular stage represents a peak of extinction. Peaks are, then, expected to occur approximately every fourth stage, albeit with considerable variance. In fact, their actual distribution in the Phanerozoic does not significantly deviate from this expectation of random-walk model[52]. Given the assumption of equal stage durations for the Triassic to early Cretaceous and given also 6.2 Myr as the average stage duration in the Guadelupian to Quaternary, the 26-Myr periodicity of extinction peaks in that time interval also does not significantly deviate from expectation. (The average stage duration is considerably longer in the Palaeozoic and, therefore, 35–40-Myr periodicity can be expected for this era, which may explain the misfit between Palaeozoic and post-Palaeozoic data reported by Raup and Sepkoski[1].)

On the other hand, the Pliensbachian, Bajocian, Tithonian and Hauterivian rather consistently stand out as significant events in Table 1. These stages, however, also represent peaks of family origination[52], despite the absence of overall correlation between extinction and origination[53]. This may suggest that they were simply longer than adjacent stages, such a hypothesis is especially plausible for the Bajocian, as it also includes the Aalenian in the stratigraphical framework of Sepkoski's compendium.

There are few stages that do not appear as maxima of family extinction in Table 1, regardless of timescale and definition, although some of them might, given other randomizations of the timescale (only three randomizations were made for each of the two timescales[32,33] considered here). Only the Maestrichtian event stands out regardless of timescale and extinction metric. The late Permian maximum shifts from the Guadelupian to Dzhulfian under some timescales, and both of them depart strongly from the regression line of probabilistic extinction rate over time. It is a subjective matter whether the late Triassic maximum is placed in the Carnian, Norian or Rhaetian (in fact, both the Carnian and Norian strongly depart from the regression, whereas the Rhaetian was probably the shortest and, hence, gains prominence if the extinction metric is normalized for time). Under time-normalized extinction metrics, virtually each Jurassic and Cretaceous stage may be a period of mass extinction. If extinction probability per Myr is considered, there seems to be no important event during the 65 Myr of the Cenozoic (the range of variation of the extinction metric does not exceed 0.002 in the Cenozoic, whereas it is an order of magnitude wider in the late Cretaceous); and there is only one late Jurassic event throughout the Jurassic and early Cretaceous (~120 Myr), given some timescales.

When plotted against absolute time (Fig. 1), the pattern of mass extinctions becomes even more ambiguous. Even under the same definition of extinction maxima, there is much uncertainty about their timing. To overstate the case, the Pliensbachian and Bajocian events (if there were such) may be as close to each other as 5 Myr or as far apart as 40 Myr according to Harland *et al.*[33] (this range is somewhat smaller under the Odin timescale[32]). If the extinction metric is normalized for time, there is almost no invariance in time distribution of major events

Thus, the assumption that all major mass extinction events are correctly identified and that no event is either missing from or redundant in the list[2,24] is absolutely unwarranted. Non-parametric testing is, therefore, appropriate. The test developed by Raup and Sepkoski[1] and Rampino and Stothers[12], however, is very liberal, for it is insensitive to the absence of predicted events. Hence, the test is not expected to reject the claim for periodicity even if some minor peaks (for example, Olenekian, Bajocian, Callovian, Hauterivian, middle Miocene) are no longer regarded as true mass extinctions. Some extinction metrics pass that test for various cycle lengths under certain timescales (for example, events defined as in Table 1*D* fit the 26-Myr periodicity under the timescale of Harland *et al.* and no other timescale considered herein). Correlation to various external cycles could, then, be sought and *ad hoc* explanations given for absence of mass extinctions from where they should be (for example, absence of any early to middle Jurassic, early Cretaceous, and Cenozoic events in Table 1*D*). If, however, such absences are considered real, or if minor events are also taken into account, the appearance of periodicity vanishes in most cases.

It is crucial that what is a matter of interpersonal agreement is not accepted as a matter of discovery. There may be periodicity in late Permian to Quaternary mass extinctions, but we only know that there were periods (not necessarily short) of increased extinction in the late Permian, late Triassic, late Cretaceous and perhaps also late Jurassic and mid-Cretaceous. The exact timing of these events and what other events, if any, are to be considered mass extinctions, are subject to arbitrary decisions. It is those subjective decisions that result in the appearance of periodicity of mass extinctions However, even if the objective pattern of mass extinctions did indeed appear periodic, this might be due to combined effects of independent processes rather than to a single causal mechanism[51,52]. Hence, the biological and geological context of each event must be evaluated on its own.

I thank Karl Flessa, David Jablonski and Jennifer Kitchell for an opportunity to read their unpublished manuscripts, and Joe Ghiold and Max Hecht for assistance and comments.

Outer hair cells in the mammalian cochlea and noise-induced hearing loss

A. R. Cody & I. J. Russell

MRC Neurophysiology Group, School of Biological Sciences, University of Sussex, Falmer, Brighton BN1 9QG, UK

Hair cells in the mammalian cochlea transduce mechanical stimuli into electrical signals leading to excitation of auditory nerve fibres[1]. Because of their important role in hearing, these cells are a possible site for the loss of cochlear sensitivity that follows acoustic overstimulation[2,3]. We have recorded from inner and outer hair cells (IHC, OHC) in the guinea pig cochlea during and after exposure to intense tones. Our results show functional changes in the hair cells that may explain the origin of noise-induced hearing loss. Both populations of hair cells show a reduction in amplitude and an increase in the symmetry of their acoustically evoked receptor potentials. In addition, the OHCs also suffer a sustained

depolarization of the membrane potential. Significantly, the membrane and receptor potentials of the OHCs recover in parallel with cochlear sensitivity as measured by the IHC receptor potential amplitude and the auditory nerve threshold. Current theories of acoustic transduction[4–6] suggest that the mechanical input to IHCs may be regulated by the OHCs. Consequently, the modified function of OHCs after acoustic overstimulation may determine the extent of the hearing loss following loud sound.

Pigmented guinea pigs (200–250 g) were anaesthetized with pentobarbital sodium, Operidine and Droleptan (Janssen) before the animals were prepared for intracellular recording[1,7]. Acoustic test stimuli were delivered in a closed sound system with a Beyer DT48 earphone and the intense tones delivered by a Bruel and Kjaer 12.5-mm condenser driver (Type 4134). The frequency of the intense tone was fixed at 12.5 kHz (110 dB sound pressure level (SPL), 225 ms), which has been shown[3] to be the most effective stimulus for producing a loss of neural sensitivity in the region of the cochlea (15–20 kHz) from which the majority of IHCs were recorded. For the duration of the experiment cochlear sensitivity was assessed by the threshold response of the auditory nerve to gated tones (1 ms rise time). Identification of the hair cells depended on their electrical properties and their recording locations, which were correlated by intracellular dye marking. After a hair cell had been impaled, normal voltage responses were recorded to either a 600-Hz continuous tone (85 dB SPL), or in the case of IHCs, a gated tone (40–60 dB SPL) close to the characteristic frequency (c.f.) of the cell. The animal was then exposed to the 12 5-kHz tone at 1-s intervals and the responses of the hair cell recorded.

IHC receptor potentials (Fig. 1*a*) generated in response to low-frequency tones can reach 30 mV and demonstrate a depolarizing asymmetry as the intensity increases. As the stimulus frequency increases, the amplitude of the phasic component of the receptor potential decreases at about 6 dB per octave, probably as a direct result of the low-pass electrical properties of the hair cell membrane[1]. For high stimulus frequencies, at or near the c f. of the cell, the receptor potential produced by IHCs is recorded as a direct current (d.c.) component that can reach 15 mV in amplitude (Fig. 1*b*). It is thought that this depolarizing potential generated across the hair cell membrane controls transmitter release at the afferent synapse and subsequent afferent fibre excitation[1,7].

Resting membrane potentials of OHCs in the basal coil of the cochlea are significantly larger than those of IHCs (typically −70 to −85 mV compared with −45 mV) whereas the receptor potentials in response to low-frequency stimuli reach maxima of only 8–10 mV. With low-frequency stimulation the receptor potentials of OHCs are symmetrical at low intensities but, in contrast to IHCs, grow in the hyperpolarizing phase as the stimulus intensity increases (Fig. 1*c*) For tones close to the presumed c.f. of the cell no d c. receptor potential is recorded for stimulus levels less than 90 dB SPL (Fig. 1*d*). A small depolarizing d.c. component (up to 5 mV) may be recorded but only when the intensity of the stimulus approaches 110 dB SPL. It thus appears that the transfer characteristics of the IHCs and OHCs in the basal turn are quite different.

At the onset of the 12.5 kHz exposure tone (Fig. 2*a*), the IHC depolarizes to a level 10–20 mV above the resting potential at a rate that is indistinguishable from the rise of the tone burst (1 ms). The d.c. receptor potential then adapts for the remainder of the exposure. In a number of animals the adaptation demonstrated two separate stages (Fig. 2*d*), an initial rapid phase with a time constant of about 10 ms and then a slower phase where the cell repolarized at a rate of approximately 1 mV s^{-1}. At the offset of the loud tone, the membrane rapidly repolarizes to the pre-exposure resting potential with no obvious sustained elevation of the membrane potential (Fig. 2*d*). The d.c. voltage responses to the test tone at their best frequencies are reduced after the loud tone and recover between the acoustic overstimulations in a manner that can be described by a single exponential function with a time constant of about 200 ms. With multiple presentations of the loud tone these voltage responses show a cumulative decrease in amplitude This loss of sensitivity is also seen as a decrease in the amplitude of the compound action potential recorded from the auditory nerve; that is, with successive loud tones the cochlear shows a progressively greater loss of sensitivity.

The growth of the depolarizing d.c. receptor potentials recorded from the OHC (Fig. 2*b*) during the loud tone differs from the IHC responses in that they demonstrate a considerably longer time constant (4–5 ms) at the onset. In addition, the OHC membrane potential shows no sign of adapting but continues to depolarize during the tone. At the offset the OHC repolarizes, but only to a level above the pre-exposure or control value. With multiple exposures this results in a cumulative depolarization of the cell. For the cell shown in Fig. 2*c*, this depolarization accumulates at the rate of 0.3 mV after each presentation However, the membrane potential does return to the control level if sufficient recovery time is allowed between the 12.5-kHz tones.

The recovery of the IHC d.c. responses to tones close to their best frequencies is closely correlated ($r^2 = 0.97$) with the repolarization of the OHCs following an intense tone (Fig. 3) OHCs in the basal turn of the cochlea do not generate voltage responses to tones at the best frequencies of the adjacent IHCs, so it was not possible for us to compare the recovery in sensitivity of the OHCs with their membrane potentials at these frequencies. However, we were able to make this comparison at low frequencies where it was possible to monitor the phasic voltage responses of OHCs and IHCs to 600-Hz continuous tones before, during and after exposure to intense tones. The voltage responses of OHCs (Fig. 2*b*) were reduced following the intense tones and recovered in parallel with the repolarization of the membrane potential. The simplest explanation for this reduction

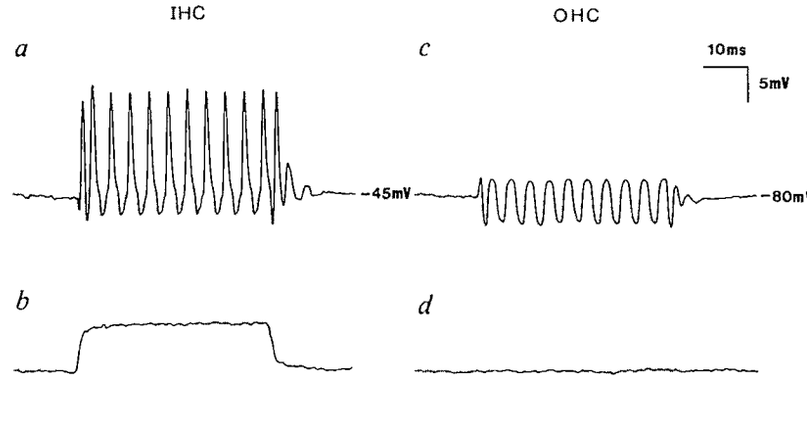

Fig. 1 Receptor potentials of an IHC and OHC recorded in the basal coil of the guinea pig cochlea in the same animal with the same electrode. *a*, *b*, Intracellular recordings from IHCs in response to a gated 200-Hz tone (*a*) and 16-kHz tone (*b*) at intensities of 85 dB SPL and 65 dB SPL respectively In both cases an asymmetrical depolarizing potential is generated during the acoustic stimuli Recordings from identified OHCs at 85 dB SPL show hyperpolarizing potentials during the 200-Hz tone (*c*) and no depolarizing potential during the 16-kHz (65 dB SPL) (*d*) presentation OHC responses are in phase with the cochlear microphonic recorded at the round window while the response of IHC phase leads the OHCs by about 90° for a stimulus frequency of 200 Hz. The transients associated with the onset and offset of the hair cell response are derived from transients in the gated tone. All records are single traces and are not averaged.

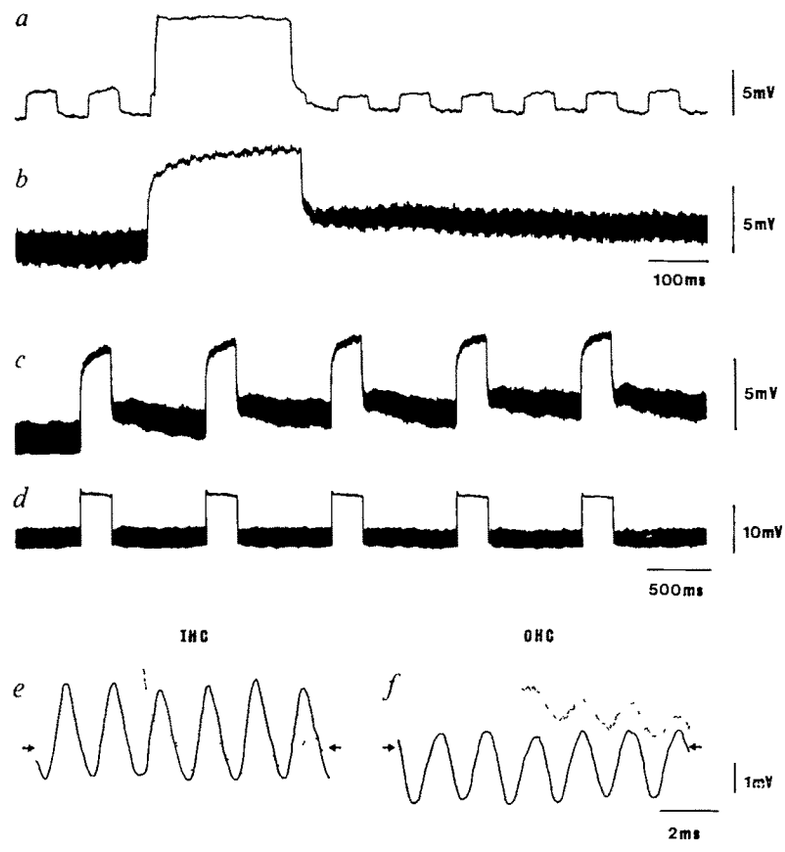

Fig. 2 *a*, Receptor potentials recorded from an IHC in response to a 16-kHz test tone (60 dB SPL) and a single 225-ms 12 5-kHz exposure. The voltage responses of the IHC to the 16-kHz tones decrease immediately following the loud tone and then recover with a time constant of approximately 200 ms. *b*, OHC voltage responses to a continuous 600-Hz tone (85 dB SPL) and a single presentation of the 12.5-kHz tone. The OHC continues to depolarize during the loud tone and at the offset, the phasic component of the receptor potential is reduced in comparison with the pre-exposure amplitude. It then recovers with a time course similar to that of the IHC. *c*, *d*, Voltage responses recorded in OHC and IHC respectively following five successive exposures to the loud tone. The IHC (*d*) demonstrates no sustained elevation of the membrane potential while the OHC (*c*) is progressively depolarized with each exposure *e*, IHC receptor potential evoked by a 600-Hz (85 dB SPL) tone before (continuous line) and immediately after acoustic overstimulation (dotted line) The latter demonstrates a decrease in amplitude and an increase in symmetry of the receptor potential around the resting membrane potential (arrow) and a phase lag when compared with pre-exposure recordings The most significant decrease in amplitude is in the depolarizing phase This decrease is not associated with a change in the resting membrane potential *f*, OHC receptor potential recorded before (continuous line) and immediately following (dotted line) the loud tone. The decrease in amplitude and increase in symmetry of the OHC receptor potential is qualitatively similar to that recorded for the IHC but the OHC also demonstrates a prolonged depolarization of the membrane potential that recovers in parallel with the sensitivity of the receptor potential. There is no obvious phase change in the waveform as recorded in the IHC. In contrast to the IHC, the OHC shows a greater loss of amplitude for the hyperpolarizing phase of the receptor potential. All records are single traces with no averaging

is a reduction in the driving voltage for the transducer current as a result of the OHC depolarization. However, measurements of the membrane impedance of the OHCs after the loud tone showed that the depolarization was not associated with an obvious conductance increase. It is possible that the decrease in the OHC receptor potential amplitude is the result of an increase in the intracellular levels of cations, where cation influx exceeds cation efflux during the intense tone There is a corresponding, but smaller, reduction in the amplitude of the IHC phasic response after the loud tone (Fig. 2*d*), but in contrast to the OHCs this was not associated with a persistent depolarization of the IHC membrane potential. Furthermore, it was clear that the voltage responses of IHCs were more vulnerable to acoustic overstimulation at their best frequency.

For both groups of cells the reduction in amplitude of their voltage responses to low frequency tones is greatest for one particular phase, depolarizing for the IHC (Fig. 2*e*) and hyperpolarizing for the OHC (Fig. 2*f*), which resulted in the increased symmetry of their waveforms. A phase delay of the IHC receptor potential of about 60° when compared with control responses was also recorded (Fig. 2*e*).

The primary source of mechanical input to cochlear hair cells is the relative shear between the tectorial membrane and their apical surfaces caused by basilar membrane motion during rarefactions (excitatory) and compressions (inhibitory) of the acoustic stimuli[7,8]. This causes displacement of their stereocilia and modulation of their transducer conductances[8-10]. Current theories of cochlear transduction propose that the OHCs, by virtue of the firm attachment of their stereocilia to the tectorial membrane[11], are in a position to regulate this displacement through a bidirectional mechano-electrical feedback loop[4-6]. That is, OHCs are both detectors and effectors[12,13] and can modify the system that drives them by feedback. In contrast, the IHCs are considered as primarily sensory cells responding to the shear of their free-standing stereocilia[11] through a fluid coupling to basilar membrane motion[7,9].

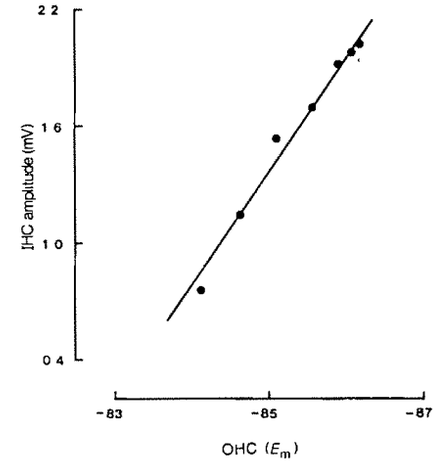

Fig. 3 OHC membrane potential (E_m) and the d.c. component of the IHC receptor potential (16 kHz) plotted over a 800-ms recovery period following exposure to a single 225-ms loud tone ($r^2 = 0.97$)

Our most important new finding is that OHCs are depolarized during and following acoustic overstimulation and that their repolarization parallels the recovery of the sensitivity of the IHCs and their afferent innervation. However, if OHCs are the protagonists in a mechano-electrical feedback loop, we do not know if the depolarization is the primary cause of the changes we have observed in the receptor potentials of the IHCs and OHCs during noise-induced hearing loss, or if it reflects more fundamental changes. In light of recent *in vitro* experiments on cochlear hair cells, there are two possibilities worth considering. One is that the primary site of such hearing losses are mechanical structures associated with the OHCs (stereocilia[14,15] and the tectorial membrane[6]), and that the depolarization of the OHCs is a response to the way these mechanical structures function

after overstimulation. The other possibility is that the OHC depolarization is a result of a massive influx of cations during the loud tone, and that one of these (Ca^{2+}) has interacted with contractile and structural proteins in the OHC[16]. This may lead to an alteration in the coupling of the stereocilia to the tectorial membrane, thereby resulting in a decrease in the mechanical input to the IHC. In this case the animal has suffered a noise-induced hearing loss.

We thank Drs D. A. Lowe and A. R. Palmer for their helpful criticisms of this manuscript. This work was supported by a grant from the MRC. A.R.C. is a National Health and Medical Research Council (Aust.), C. J. Martin Fellow.

Epidemiological studies of the human T-cell leukaemia/lymphoma virus type I (HTLV-I), a type-C retrovirus of the human T-lymphotropic virus family, have used serological surveys to identify population subgroups possessing a high prevalence of naturally occurring HTLV-I-specific antibodies. Studies carried out to delineate the global distribution of the virus have demonstrated natural antibodies to HTLV-I in the serum of healthy donors from specific geographical areas, and have defined viral endemic areas in Japan[1–4], the Caribbean basin[5–7], Africa[8–10] and the southeastern United States[11]. Such studies have suggested that the prevalence of HTLV-I antibodies is directly correlated with age[3,12–14], is associated with the clinical syndrome of adult T-cell lymphoma[1–3,13,15–19], and is associated with transmission from mother to child[11,12,20]. A separate subtype of the human retrovirus, HTLV-II (refs 21, 22), has also been identified. The population of Israel in part comprises groups of immigrants of various ethnic and geographical origins. Because of this, and the fact that Israel has a highly developed public health system, we surmised that the ethnic groups in Israel could be used in a seroepidemiological survey of HTLV infection. The serological survey reported here demonstrates a high prevalence of HTLV-I antibodies in new immigrants from Ethiopia. This previously ethnically and geographically isolated group, the 'Black Jews' or 'Falashas', from the Gondar region in the northern rural highlands of Ethiopia, has the highest endemic rate of HTLV-I yet reported outside Japan.

Analysis of 1,048 serum samples from Israelis of different ethnic/geographical origins revealed major differences in the prevalence of antibodies to HTLV-I (Table 1). Of the 1,008 sera that were divided into ethnic groups I to VI in Table 1, 104 sera were positive for HTLV-I antibodies and 86 of these sera (83%) were donated by immigrants of Jewish Ethiopian (Falasha) descent. Thus, 37% of the sera from Ethiopian donors were positive for HTLV-I antibodies. Groups II and III, consisting of donors originating in North Africa and the Middle East, showed a 10-fold lower prevalence of antibodies to HTLV-I (4.2% and 3.7%, respectively). The remaining groups exhibited levels of prevalence (1–2%) similar to those found in non-endemic areas of Europe, the United States and the higher socioeconomic groups in urban Venezuela[11–12,23].

Serum samples that were positive for antibodies against HTLV-I in an enzyme-linked immunosorbent assay (ELISA) were further assayed in an absorption test in which the sera were preabsorbed with titrated, saturating concentrations of purified HTLV-I virion antigen, followed by assay of any non-complexed antibody in an HTLV-I ELISA. Whereas the

Table 1 Prevalence of antibodies to HTLV-I in various immigrant groups in Israel

Ethnic or geographical origin of serum donors	No. positive/ no. tested	% Positive
I, Ethiopia	86/233	36.9
II, North Africa (Morocco, Tunisia, Algeria, Libya)	7/168	4.2
III, Middle East Yemen	2/30)

Iran	1/18)	
IV, Israeli-born (Ashkenazi)	3/150	2.0
V, Western Europe (Ashkenazi)	3/265	1.1
VI, Eastern Europe (Ashkenazi)	1/83	1.2
Other	3/40	NS*

We collected 1,048 serum samples randomly from apparently healthy donors of ages 19–65 yr, male and female, in Magen David Adom (Israeli blood bank) stations, mobile stations and army camps. Blood was drawn for the purpose of routine donation of blood. Sera were obtained from clotted samples remaining after routine clinical phlebotomy. Sera were stored frozen at −70 °C and shipped on dry ice to San Diego for assay. The information collected from the blood donors included age, country or region of birth, origin (ethnic and national) of the donors and their parents, and year of immigration to Israel. For the purpose of this survey, the donors were divided into six groups of ethnic and national origin. I, Ethiopia, II, North Africa (Morocco, Tunisia, Algeria, Libya), III, Middle East (Yemen, Iraq, Iran), IV, Israeli-born (predominantly of Ashkenazi descent), V, Ashkenazis born of Western European descent, VI, Eastern European-born Ashkenazis. All serum samples were collected in the spring of 1984, before the entry of thousands of additional new immigrants from Ethiopia in October–December 1984. Antibodies against HTLV-I antigens were detected by ELISA as developed by Cytotech Inc. HTLV-I was collected from the supernatant fluid of C10/MJ2 cells (provided by Dr R. C. Gallo). Virus-producing cells were pelleted by centrifugation at 3,500 r.p.m. in a RC 3 B centrifuge and the cell-free supernatant was filtered through a 0.45-μm Millipore filter. The extracellular virus was concentrated 50-fold by Pellicon Ultrafiltration (Millipore) and the concentrated virus pelleted at 25,000 r.p.m. on a cushion of 50% Renografin (Squibb). Virus was resuspended in phosphate-buffered saline (PBS) and layered onto a 15–50% Renografin gradient. Centrifugation was for 18 h at 25,000 r.p.m. in a SW28 rotor in a OTD 50 B Sorvall Ultracentrifuge. After gradient fractionation, the virus was resuspended in PBS and pelleted for 1 h at 25,000 r.p.m. Virus purified by this procedure is exceptionally pure and contains <2% non-viral protein (by weight). Solid-phase enzyme immunoassays were used for the detection of HTLV-I antibodies. Each donor serum sample was diluted 1:100 and assayed in duplicate on three separate days. A goat anti-human IgG (heavy+light chains) conjugated to glucose oxidase was used as a second antibody. To each microtitre well was added 200 μl of an enzyme substrate consisting of 200 μl 2,2'-azino-*bis*-3-ethylbenzthiazolinesulphonic acid, 200 μl horseradish peroxidase at 1 mg ml^{-1}, 3 ml of 18% β-D-glucose, in 25 ml 0.1 M phosphate buffer *p*H 6.0, and the development of a green colour was determined at 405 nm after exactly 30 min incubation in a Multiscan (Flow Laboratories) automated spectrophotometer. A reading of twice the background reading obtained with HTLV-negative sera in the same test was considered positive. In an attempt to preclude any false-positive serum antibody determinations, all positive sera were titrated and tested in a competition assay in which the serum samples were preabsorbed with purified HTLV-I virion antigen before being retested in the HTLV-I ELISA. Aliquots (250 μl) of a 1:100 dilution of donor serum samples were mixed with 1 μg of purified HTLV-I virus in 5 μl and incubated for 60 min at room temperature on a rotary shaker. After absorption with purified virus, the virus–antibody complexes were assayed for unabsorbed antibody by solid-phase immunoassay in duplicate. As a positive control serum in these assays, we used the HTLV-I antibody-positive serum SRL-SL11, a serum from a confirmed case of adult T-cell leukaemia from Japan. Preabsorption of confirmed HTLV-I-positive sera with our purified HTLV-I preparations completely removed all reactivity from these sera.

* Serum samples from a variety of sources, data not significant.

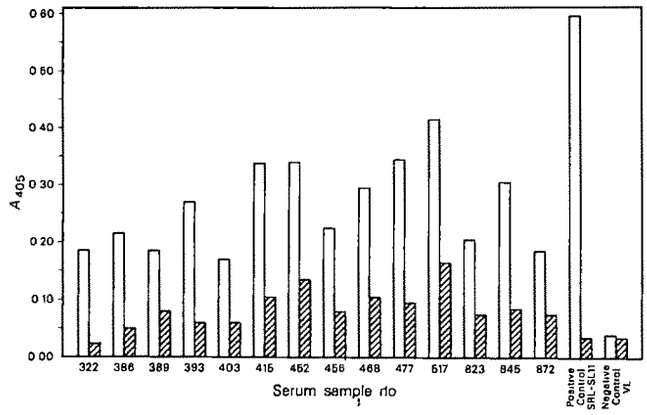

Fig. 1 Absorption of HTLV-I-positive Falasha serum samples with purified HTLV-I virions Open bars, unabsorbed serum samples, cross-hatched bars, HTLV-I-absorbed samples. See text for a discussion of the methods. All serum samples were assayed at a dilution of 1.100

antibodies that were present in most of the positive serum samples could thus be shown to be specific for HTLV-I, some 30% of the serum samples donated by Falasha individuals could not be absorbed completely with purified HTLV-I antigen. Figure 1 shows the results of absorption experiments with 14 positive Falasha serum samples; a control serum having a high titre of antibodies against HTLV-I (SRL-SL11) and an HTLV-I-negative control serum (VL) were included in the tests We found that antibodies from 4 of the 14 Falasha serum samples shown (samples 415, 452, 468 and 517) were incompletely absorbed although preabsorption with HTLV-I virions completely absorbed the antibodies from the high-titre control serum. For other serum samples (for example, samples 322, 386, 393 and 403), antibodies to HTLV-I were absorbed efficiently.

It is striking that in this serological survey of HTLV-I infection among immigrant groups in Israel, individuals of one ethnic group should display such a high prevalence of antibodies to HTLV-I and, by inference, have experienced a high frequency of virus infection. Our results show that 37% of the Black Jews of Ethiopian descent, most of them newcomers to Israel of 1 to 2 years at the time of sample collection, had been exposed to HTLV-I and had antibodies to the virus. Healthy Ethiopian-born immigrants to Israel thus have the highest frequency of exposure to HTLV-I encountered or reported to date outside Japan[4]. We are uncertain whether a similar prevalence occurs among non-Jewish Ethiopians in the highlands of that country or in other geographical rural and urban Ethiopian areas. Additional studies in other East African countries may reveal the origin of HTLV and may give rise to the isolation of variant subtypes of HTLV.

In competition immunoassays with purified HTLV-I virions as well as with purified HTLV-II virions (not shown), some HTLV-positive Falasha serum samples could be only partially absorbed. There are two possible explanations for this lack of absorption; either most antibodies in these serum samples are directed against viral core proteins p24, p19 and p15 which are not as readily available in the absorbing whole virions as are the viral envelope antigens, or the unabsorbed sera contain antibodies directed against a new subtype of HTLV which has cross-reacting antigenicities with HTLV-I, but also contains a unique antigenicity. We will investigate these possibilities using alternative methods.

HTLV-I has been shown to be associated with the development of certain T-cell leukaemias and lymphomas[2,5,13,18,19,24]. However, no direct causal relationship has been found between infection with HTLV-I and subsequent development of leukaemia or lymphoma. Unequivocal evidence linking HTLV-I infection with the development of human malignant disease has been hampered by the relatively low incidence of most cancers as well as by the low incidence of infection of most human populations with HTLV. Together with the long incubation period between exposure to HTLV and the possible development of disease, these difficulties have made prospective studies difficult because of the large number of persons who must be kept under observation. However, the Ethiopian immigrants to Israel, 37% of whom are positive for HTLV, may provide a practical population laboratory for prospective studies linking HTLV infection with subsequent disease. Studies concerning the modes of transmission of HTLV in a human population should also be feasible now that some 12,000 Ethiopian Jewish immigrants have moved to Israel and are living under improved hygienic conditions, with a modern public health system. These directions are being explored.

We thank Dr Douglas W. Blayney for critical reading of the manuscript, and Ms Kathy Wong for editorial assistance.

Thymocyte subpopulation enriched for progenitors with an unrearranged T-cell receptor β-chain gene

Ian S. Trowbridge, Jayne Lesley, Joseph Trotter & Robert Hyman

Department of Cancer Biology, The Salk Institute for Biological Studies, PO Box 85800, San Diego, California 92138, USA

The development of T cells within the thymus is not well understood. It is known that thymocytes are derived from a progenitor cell in the bone marrow, the prothymocyte[1–5], and that cells in the subcapsular area of the thymus can give rise to progeny in both the cortex and the medulla[6]. However, it is not clear whether all medullary thymocytes are necessarily derived from cortical cells[7,8]. In particular, it has been difficult to distinguish intrathymic progenitor cells. Recently, however, Lesley *et al.*[9] have defined a thymocyte subpopulation which can be isolated by treatment of the thymus with cytotoxic anti-Thy-1 antibodies and that seems to be enriched for thymocyte progenitors as measured first by its ability to repopulate transiently the thymus of an irradiated host, and second, by its high content of cells bearing Pgp-1 (refs 10, 11), a cell-surface glycoprotein of relative molecular mass 95,000 that is present on most or all prothymocytes of the bone marrow and on fetal thymocytes[29], but on only a few per cent of cells in the adult thymus[10]. We show here that the gene encoding the β-chain of the T-cell receptor for antigen, which is rearranged during T-cell ontogeny[12–15], is predominantly in the germline configuration in these cells.

In the initial series of experiments, mouse thymocytes were treated in the presence of complement with a mouse anti-Thy-1.2

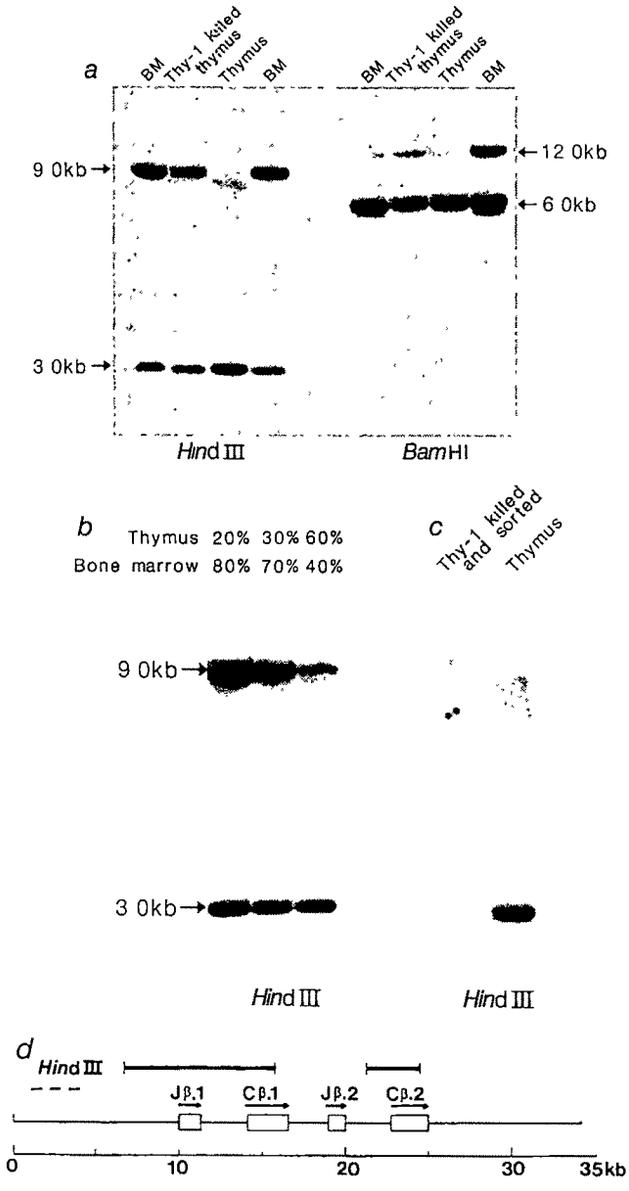

Fig. 1 *a*, Southern blots of Thy-1-killed thymus compared with bone marrow (BM) and total thymus. All lanes contained 10 μg digested DNA except the second BM sample which was 20 μg. *b*, Reconstruction experiment in which bone marrow DNA and thymus DNA were mixed in the proportions indicated. A total of 10 μg DNA was applied to each slot. *c*, Comparison of the Southern blots obtained with total thymus and Thy-1-killed thymus from which RB6-8C5-positive cells had been removed by fluorescence-activated cell sorting. Approximately 2 μg DNA from the Thy-1-killed and sorted population and 10 μg DNA from total thymus were loaded. *d*, Map of mouse germline T-cell receptor C_β-chain genes and their associated J_β segments indicating the origin of the *Hin*dIII restriction fragments observed in *a*–*c*. The map is derived from data presented in ref. 17.

Methods. Thymocytes from 50–80 C57BL/6 mice were treated with the mouse monoclonal anti-Thy-1.2 antibody HO 13.4.9[25] and complement as described in ref. 9. Briefly, $8–13 \times 10^9$ thymocytes were washed, treated with Tris-buffered ammonium chloride, and samples of 1×10^9 cells were spun down. Each cell pellet was resuspended in a total volume of 10 ml of HEPES-buffered Dulbecco's modified Eagle's medium with 2% newborn calf serum and containing tissue culture supernatant of HO 13.4.9 antibody (1:4 final dilution) and rabbit complement (1·20 final dilution). After incubation at 37 °C for 45 min, the cells were overlayed on 15 ml of Ficoll–Hypaque (Pharmacia) and centrifuged at room temperature for 25 min at 1,700*g*. The interface layer was recovered and washed. In some experiments, in which significant numbers of dead cells remained, the Ficoll–Hypaque treatment was repeated. After killing and Ficoll–Hypaque treatment, 0.2–0.4% of the input cells were recovered. A portion of the recovered cells was taken for flow cytometry (see Fig. 2 legend). High relative molecular mass DNA was prepared from the remaining cells by standard procedures and digested completely with either *Bam*HI or *Hin*dIII[26]. The digested DNA was fractionated on a 0.7% agarose gel and transferred to nitrocellulose filters. Filters were hybridized at 42 °C overnight with the ^{32}P-labelled *Eco*RI fragment of the 86T5 murine β-chain plasmid (0.25 μg; 2×10^8 c.p.m. per μg) in 40% v/v formamide, 4×S.S.C., 10% w/v dextran sulphate, 0.8×Denhart's solution, 500 μg ml^{-1} salmon sperm DNA in 7 mM Tris-HCl *p*H 7.6. Filters were washed twice for 30 min at room temperature, with 2×SSC/0.1% SDS and then washes were repeated with 0.1 SSC/0.1% SDS at 55 °C. Autoradiography was for 2–5 days.

monoclonal antibody (see Fig. 1 legend). After incubation, dead cells were removed by centrifugation over Ficoll–Hypaque and a portion of the viable cells was used to prepare high relative molecular mass DNA. The remaining cells were then stained with rat monoclonal antibodies against cell-surface antigens and analysed by flow cytometry using as a second-stage reagent a fluoresceinated goat anti-rat IgG which does not crossreact with mouse IgG. This made it possible to determine the cell-surface phenotype of the cell population in the presence of the mouse anti-Thy-1 antibody used for cytotoxic ablation. Concomitantly, by hybridizing DNA from these cells by the method of Southern[16] with a ^{32}P-labelled mouse T-cell receptor β-chain probe, it was possible to determine whether the T-cell receptor β-chain gene had undergone rearrangement in these cells. Figure 1*a* shows a typical experiment in which DNA from bone marrow, unfractionated thymus, and thymocytes surviving treatment with the cytotoxic anti-Thy-1 antibody had been digested with either *Hin*dIII or *Bam*HI restriction enzymes. In both cases, two bands hybridized to the β-chain probe, 86T5, which is an *Eco*RI cDNA fragment spanning the *V–J* (variable-joining) and *C* (constant) regions of the gene[14]. Comparison of the pattern obtained with total thymus and bone marrow shows the clear-cut distinction between the non-rearranged and rearranged genes. Whereas the higher relative molecular mass band obtained with both restriction enzymes is sharp when bone marrow DNA is probed, the total thymus gives a heterogeneous smear of bands. Most strikingly, the autoradiograph also clearly shows that the T-cell receptor β-chain gene in the 0.5% of thymocytes surviving treatment with anti-Thy-1 antibody and complement is predominantly non-rearranged. From reconstruction experiments using bone marrow and total thymus DNA in different proportions (Fig. 1*b*), it can be estimated that >80% of the T-cell β-chain genes in this thymocyte subpopulation are non-rearranged. The pattern of bands obtained from the *Hin*dIII digests are particularly informative. Previous work has shown that the 9-kilobase (kb) fragment extends upstream of the $J_\beta 1$ segment to the 3′-end of the $C_\beta 1$ gene (Fig. 1*d* and refs 17–19). Thus, this restriction fragment is variably reduced in size during diversity-joining rearrangements in the T-cell receptor β1-chain cluster. In contrast, the 3-kb fragment is derived from the *C* region of the β2-chain gene and is unaffected by rearrangements within the β2-chain gene cluster. Consequently, deletions in the 9-kb fragment serve as an indicator of all rearranged β1-chain genes, whereas the 3-kb fragment derived from the $C_\beta 2$ region serves as an internal control.

The antigenic phenotype of the thymus subpopulation was determined with two objectives in mind: first, to determine whether the phenotype of these cells differed from that of the bulk population of thymocytes, and second, to estimate the extent to which the cells surviving treatment with anti-Thy-1 antibody may be derived either from non-lymphoid thymic tissue or from mature haematopoietic cells derived from either blood

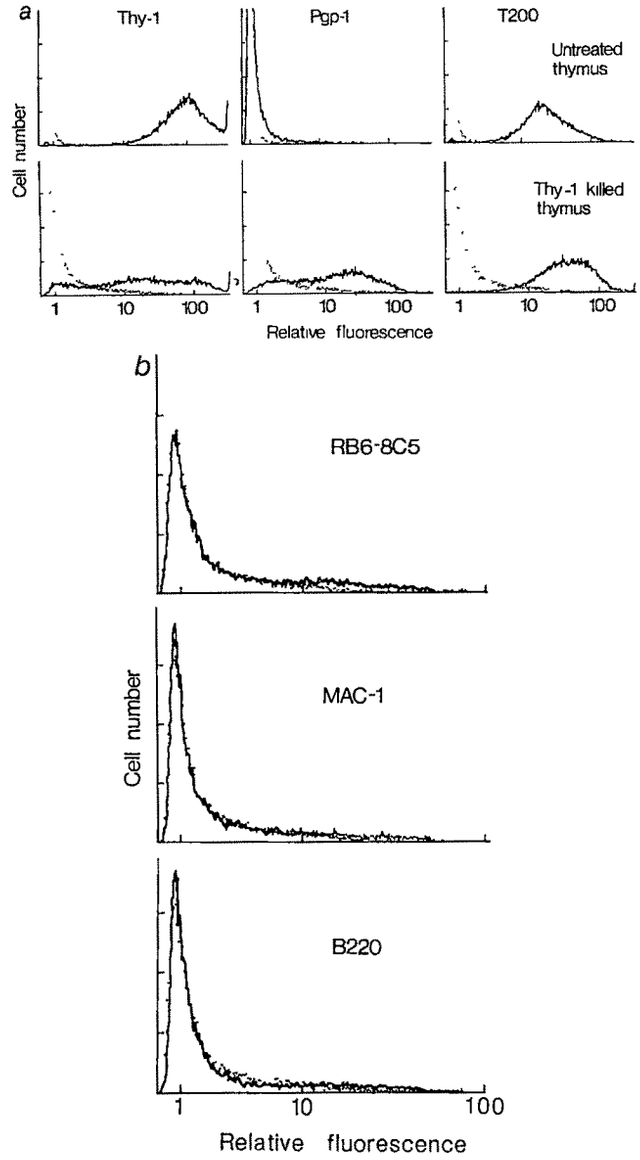

Fig. 2 Surface antigens of the anti-Thy-1-killed thymocyte population analysed by flow cytometry. Specific fluorescence (solid curves) is expressed relative to the peak of the background population in which normal tissue culture medium was substituted for monoclonal antibody containing tissue culture supernatant (dotted curves). *a*, Relative to untreated thymus, Thy-1-killed thymocyte populations show heterogeneous staining for Thy-1 with a subpopulation at or near background levels. Thy-1-killed thymocytes are enriched in highly fluorescent Pgp-1^+ cells and are essentially all $T200^+$. *b*, Most cells in Thy-1-killed populations do not stain with antibodies recognizing mature granulocytes (RB6-8C5), macrophages and monocytes (Mac-1), or B cells (B220) Ordinate: cell number

Methods. Aliquots of 1×10^6 untreated thymocytes and $2\text{–}5\times10^5$ thymocytes recovered after cytotoxic treatment with the mouse monoclonal anti-Thy 1.2 antibody, HO 13.4.9, and centrifugation on Ficoll-Hypaque as described in Fig. 1 legend ('Thy-1-killed thymocytes') were stained with tissue culture supernatants of the rat anti-mouse hybridomas C22/22.7.1.1 (ref. 27) (anti-Thy-1), IM7.8.1 (ref. 10) (anti-Pgp-1), I3/2.3[20] (anti-T200), RB6-8C5, which recognizes mature granulocytes (R. Coffman *et al.*, in preparation), M1/70.15[22] (anti-Mac-1), and RA3-3A1[21] (anti-B220), followed by staining with a fluorescein-labelled goat anti-rat immunoglobulin which had been absorbed to remove antibodies reacting with mouse immunoglobulin (Hyclone). Flow cytometry was carried out on the Salk Institute flow microfluorimeter. Data were stored as list mode data files which were gated to remove dead cells stained with propidium iodide as detected in the red channel. Fluorescein fluorescence in the green channel was log-compressed with a three-decade logarithmic amplifier before analog to digital conversion as previously described[28].

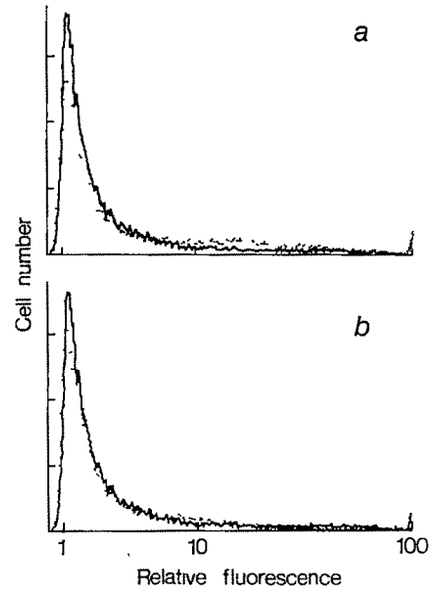

Fig. 3 Thy-1 population sorted for RB6-8C5-negative cells. *a*, Sorted (solid curve) and not sorted (dotted curve) Thy-1-killed thymocytes stained for RB6-8C5. The sorted population is depleted in cells staining with the RB6-8C5 antibody *b*, Sorted cells stained with RB6-8C5 (solid curve) compared with the background staining of the Thy-1-killed population which was not sorted (dotted curve). Specific staining approaches background levels.

Methods. Thymocytes were treated as described in the legend to Fig. 1. Thy-1-killed cells (1.4×10^7) from the same experiment as that illustrated in Fig. 2 were stained with RB6-8C5 antibody and fluorescent goat anti-mouse immunoglobulin. These stained cells were sorted on the Salk Institute BCS-176 cell sorter with the instrument optimized for the rapid selection of RB6-8C5-negative cells using anti-coincidence logic in the green fluorescence channel. The cells were sorted at a rate of 2,500 cells s^{-1}, deflecting three drops per event. The cells recovered from the sort were restained with various monoclonal antibodies and fluorescent goat anti-rat immunoglobulin as described in Fig. 2 legend.

or parathymic lymph nodes that may be present in the thymocyte preparations. The antigenic profile which has been consistently seen in four such replicate experiments is shown in Fig. 2. The data show that essentially all the cells express T200 glycoprotein[20] on their cell surface, suggesting that there are few, if any, non-lymphoid cells in the subpopulation of cells surviving treatment with anti-Thy-1 antibody. Moreover, the surviving cell population is enriched for Pgp-1^+ cells, consistent with the hypothesis that Pgp-1 glycoprotein is expressed on thymocyte progenitor cells. Most cells express Thy-1 but at levels much lower than the bulk thymocyte population and further analysis of these data indicates that a small subpopulation of cells expresses little or no Thy-1. With regard to the possible contribution of cells from either blood or parathymic lymph nodes, in this particular experiment ~5% of cells stained with a monoclonal antibody against B220, which is thought to be specific for B cells[21]; 7% stained with a monoclonal antibody against Mac-1, which is considered specific for myeloid cells[22]; and 13% stained with monoclonal antibody RB6-8C5, which is known to stain mature granulocytes (R. Coffman, J. Carty, L. Gemmell, J. Lesley, I. Weissman and D. Rennick, in preparation). On the basis of these results, it can be estimated that in this experiment the maximum contribution of non-T cells in the subpopulation of the thymus surviving treatment with anti-Thy-1 antibody is 25%. This is a maximum estimate since it is not known whether the RB6-8C5 monoclonal antibody reacts with thymocyte progenitor cells. It should also be noted that any contaminating mature T cells from blood or lymph nodes would yield DNA in which the T-cell receptor genes are rearranged.

These results make it unlikely that most of the non-rearranged T-cell receptor β-chain genes found in the subpopulation of

cells surviving treatment with anti-Thy-1 antibody were derived from cells other than thymocytes. However, to address this question more rigorously, an additional set of experiments were carried out. Thymocytes were first treated with anti-Thy-1 antibody and complement and then the viable cells remaining were isolated and stained with monoclonal antibody RB6-8C5. The cells were then fractionated by fluorescent cell sorting to remove cells staining with monoclonal antibody RB6-8C5. As shown in Fig. 3, this procedure reduced the number of cells staining with this antibody approximately 10-fold. The Thy-1 and Pgp-1 profiles of the sorted and nonsorted populations were essentially identical. When DNA from the sorted cells was digested with *Hin*dIII and blotted, it was clear that most cells had unrearranged β-chain genes although the limited amount of DNA available for analysis precluded precise quantitation (Fig. 1*c*).

In conclusion, we have shown that the subpopulation of thymocytes surviving treatment with anti-Thy-1 antibody and complement consists largely of cells in which the gene for the β1-chain of the T-cell receptor has not yet undergone rearrangement. This direct evidence that in the mouse the rearrangement of the β-chain gene is an intrathymic event is consistent with previous data from studies in man[23,24]. The cell-surface phenotype of these surviving cells indicates that the great majority of them are bona fide thymocytes that express Pgp-1 glycoprotein. We believe that the previous data showing that thymocyte subpopulations enriched in Pgp-1$^+$ cells can transiently repopulate the thymus and that Pgp-1$^+$ cells are found in abundance in early fetal thymus, together with the observations in the present paper, indicate that, although this population is still heterogeneous, thymocyte progenitor cells are enriched in this subpopulation of thymocytes. It is interesting that recently a thymic subpopulation representing 2–4% of unfractionated cells has been isolated in which the the β-chain genes have undergone rearrangement but the α-chain genes have not (M. Davis *et al.*, personal communication). Although other explanations are possible, these cells may represent the next stage of development of the progenitor cells identified in the present studies.

We thank G. Evans, D. Shackelford and S. Hedrick for helpful comments on the manuscript. Steve Hedrick provided the 86T5 plasmid and Bob Coffman provided the monoclonal antibody RB6-8C5. This work was supported by NCI grants CA 17733 (I.S.T.) and CA 13287 and CA 25893 (R.H.) and by funds from the Armand Hammer Foundation.

Similarities between interleukin-2 receptor number and affinity on activated B and T lymphocytes

John W. Lowenthal*, Rudolf H. Zubler†§, Markus Nabholz‡ & H. Robson MacDonald*

* The Ludwig Institute for Cancer Research, Lausanne Branch, and † Immunology Unit and ‡ Genetics Unit, Swiss Institute for Experimental Cancer Research, 1066 Epalinges, Switzerland

Interleukin-2 (IL-2) is a T-cell-derived polypeptide hormone of 133 amino acids which exerts its growth-promoting activity via a surface receptor[1]. Originally, IL-2 was believed to be a unique growth factor for activated T cells[2]; more recent studies, however, have demonstrated that certain B-cell tumours[3] as well as normal activated B lymphocytes[4–6] express a surface molecule which is recognized by monoclonal antibodies directed against the IL-2 receptor. Furthermore, we[7] and others[6] have shown recently that activated B cells proliferate in response to either immunoaffinity-purified[8] or recombinant[9] IL-2. These controversial findings prompted us to undertake a detailed quantitative comparison of IL-2 receptor expression on activated B and T cells. We show here, using biosynthetically labelled IL-2 (^{3}H-IL-2) and anti-IL-2 receptor antibody (^{3}H-PC61) that activated B and T cells express both high-affinity (apparent dissociation constant, $K_d \sim 20$ pM) and low-affinity ($K_d \sim 1{,}000$ pM) IL-2 receptors. Binding of IL-2 to both classes of receptor is inhibited by the monoclonal anti-IL-2 receptor antibody PC61. B blasts express half as many total IL-2 binding sites or PC61 binding sites as T blasts, and the ratio of the number of low- to high-affinity receptors for each cell type is ~10:1. Immunoprecipitation analysis of surface-labelled blasts indicates that B and T cells have IL-2 receptors of similar relative molecular mass. Taken together, these data suggest strongly that IL-2 can act as a growth hormone for both B and T lymphocytes.

To quantitate and compare the number of IL-2 receptors expressed on activated B and T cells, we used ^{3}H-IL-2 in equilibrium binding assays[2]. Previous studies have shown that murine B cells activated with lipopolysaccharide (LPS) alone do not respond to[7], nor do they express detectable receptors for, IL-2[2,7]; however, B cells activated with LPS and anti-immunoglobulin antibodies (anti-Ig)[7] bind ^{3}H-IL-2 in a specific manner (Fig. 1*A*). Scatchard plot analysis of the specific binding data (using the Scatfit computer program) demonstrates that the activated B cells, like T cells, express two classes of IL-2 receptor. Figure 1*B* shows that the B blasts express 2,000 high-affinity IL-2 receptors ($K_d = 22$ pM) and ~10 times as many receptors of relatively lower affinity ($K_d = 1{,}330$ pM). Although the numbers of both classes of receptors expressed by concanavalin A (Con A)-activated T cells are about twice those on LPS/anti-Ig-activated B cells, the K_d values are very similar (17 and 1,270 pM for high- and low-affinity receptors, respectively). Binding of ^{3}H-IL-2 to low-affinity receptors is saturable at an IL-2 concentration of 3–5 nM (not shown); furthermore, it can be inhibited either with unlabelled IL-2 or with monoclonal antibody PC61 (ref. 10; Fig. 1*A*) but not with monoclonal antibodies to other cell-surface antigens (not shown). Although previous studies[2] reported that activated T cells express a single class of high-affinity receptors ($K_d = 5$–20 pM), a more recent report by Robb *et al.*[11] demonstrated that a second class of receptors of lower affinity is also detectable on murine and human T cells when much higher concentrations of IL-2 than those previously tested are used. Our results with various cell types (Table 1) including human phytohaemagglutinin (PHA)-induced blasts (not shown) show a 50–100-fold difference in K_d between the two classes of IL-2 receptor and an 8–14-fold excess of low- over high-affinity receptors, which is in close quantitative agreement with studies involving other hormone systems such as epidermal growth factor[12,13] and insulin[14,15]. Furthermore, both

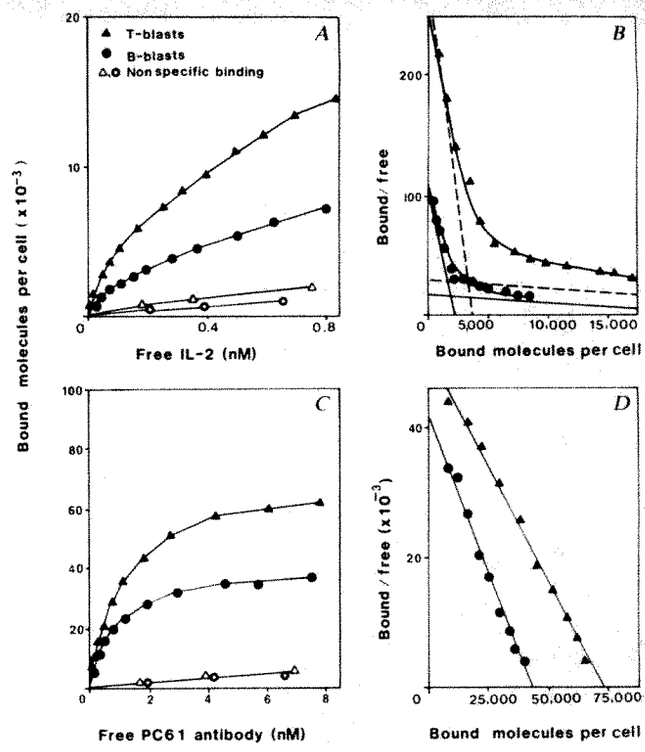

Fig. 1 Comparison between equilibrium binding of IL-2 and PC61 on B (●) and T(▲) blasts. In the presence of either excess unlabelled IL-2 or PC61 antibody, the binding of ^{3}H-IL-2 was reduced by 90–95% at all IL-2 concentrations tested (*A*, open symbols). The binding of ^{3}H-PC61 was inhibited by excess unlabelled PC61 (*C*, open symbols) but not by unlabelled IL-2 (not shown). Specific equilibrium binding (solid symbols) of IL-2 and PC61 is shown in *A* and *C*, respectively, after subtraction of nonspecific binding (open symbols). Scatchard plot analyses of these data were performed using a weighted least-squares curve-fitting computer program[22] (*B* and *D*). For IL-2 binding (*B*), the computer chose a two-binding-site model over a one-site model as the best fit to the experimental data. Broken lines (T blasts) and solid lines (B blasts) represent the computer-generated high- and low-affinity binding components. Similar results were obtained in three independent experiments.

Methods. B blasts were prepared as described elsewhere[7] by culturing purified C57BL/6 splenic B cells in the presence of LPS, anti-Ig beads and 10% EL4 supernatant (SN). T blasts were prepared by culturing spleen cells from the same mouse strain at a concentration of 2×10^6 ml^{-1} in the presence of 1.5 μg ml^{-1} Con A and 10% EL4 SN. Both cell types were collected after 4 days, centrifuged on a Ficoll/Hypaque gradient and washed extensively. The preparation of affinity-purified ^{3}H-IL-2 and the IL-2 binding assay have been described in detail[2,8]. In the experiments described here, all incubations were carried out at 4 °C in the presence of azide. For PC61 binding, aliquots of 10^6 cells were incubated for 20 min (equilibrium binding occurs within 15 min) in the presence of various amounts of protein A–Sepharose-purified ^{3}H-PC61 (ref. 10) in a volume of 200 μl. Before the antibody binding assay, cells were pre-incubated in the presence of 10% normal rat serum in order to block nonspecific binding of PC61 via Fc receptors. Free and cell-bound PC61 were measured by liquid scintillation counting after centrifugation through a paraffin–silicon oil gradient[2]. The number of bound IL-2 and PC61 molecules per cell was calculated given the specific activities of 2,500 c.p.m. ng^{-1} and 210 c.p.m. ng^{-1}, respectively. The M_r of IL-2 and PC61, as judged by SDS-PAGE, is 15K and 170K, respectively.

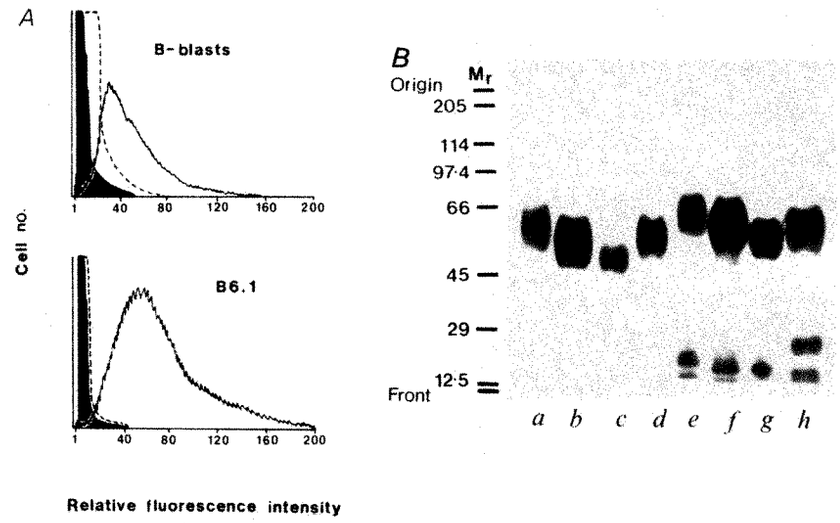

Fig. 2 *A*, Most activated B and T cells express the PC61 antigen. Solid lines represent the fluorescence profile of the PC61 antigen distribution (B blasts on gain 16; B6.1, gain 4); broken lines show the level of nonspecific staining after incubation in the presence of excess unlabelled PC61; shaded areas show background staining with avidin-fluorescein isothiocyanate (FITC) alone. In B-blast preparations, Thy-1-positive cells were not detected above background fluorescence. In addition, we have shown previously[7] by immunoperoxidase staining that cultures of B blasts contain >97% immunoglobulin-positive cells and <0.3% Thy-1-positive cells. The mean fluorescence intensity of B6.1 cells was about five times higher than for B blasts when normalized to the same gain, which is consistent with the data shown in Table 1. *B*, PC61 immunoprecipitates membrane components of similar M_r from different types of IL-2-responsive cells. Electrophoretic patterns (lanes *a–d*, non-reduced; *e–h*, reduced conditions) were obtained after immunoprecipitation with PC61 of lysates obtained from various types of IL-2-dependent cells: B1.8 (*a*, *e*), Con A blasts (*b*, *f*), B blasts (*c*, *g*) and BD2.10 (*d*, *h*). Lane *g* was exposed for 7 days, and all other lanes for 4 days.

Methods. *A*, B blasts were prepared as described in Fig. 1 legend, centrifuged on a Ficoll/Hypaque gradient, washed and pre-incubated in 10% normal rat serum. 5×10^5 B blasts or B6.1 cells were then incubated (20 min at 4 °C) in 100 μl of phosphate-buffered saline (PBS) containing 2 μg of biotinylated PC61 antibody in the presence or absence of 100 μg unlabelled PC61. The cells were washed, incubated for 20 min with avidin-FITC and analysed on a fluorescence-activated cell sorter (FACS II; Becton and Dickinson) gated to exclude non-viable cells[23]. *B*, Cells ($1–2\times10^7$) were surface-labelled with ^{125}I by the glucose oxidase–lactoperoxidase method of Hubbard and Cohn[24] as modified by Luescher *et al.*[25]. The labelled cells were lysed in 0.5 ml of cold 1% recondensed Triton X-114 in 50 nM Tris-HCl (*p*H 7.7) containing 0.3 M NaCl and 5 mM EDTA. The aqueous and detergent phases were separated according to Bordier[26]. Triton-insoluble material was removed by centrifugation of the lysates for 3 min at 4 °C. The lysates were heated to 30 °C for 1 min, then spun in an Eppendorf centrifuge at room temperature for 1 min. The aqueous phase was removed, the detergent phase re-dissolved in 0.5 ml of cold buffer and the separation repeated. The lysates were pre-cleared for immunoprecipitation by sequential addition of 5 μl normal rat serum, 20 μl rabbit anti-rat immunoglobulin and 12.5 μl protein-A–Sepharose 4B (twice), each step followed by incubation for 20 min on a rotating mixer. The pre-cleared lysates were then incubated for 60 min with purified PC61 antibody coupled to Sepharose 4B, followed by extensive washing of the lysates with two buffers: (1) 10 mM phosphate buffer (*p*H 8.2) containing 0.05% SDS, 0.05% deoxycholate, 0.5% Nonidet P-40 (NP40) and 10 mM EDTA; and (2) 0.12 M Tris-HCl (*p*H 8.2) containing 0.5 M NaCl, 0.5% NP40 and 10 mM EDTA. The immunoprecipitates were analysed by SDS-PAGE according to Laemmli[27] on 7.5–15% gradient gels. Samples were reduced with 0.1 M dithiothreitol and denatured by boiling in 4% SDS. After electrophoresis, the gels were autoradiographed at −70 °C on Kodak XAR film. M_r standards were: myosin (205K), β-galactosidase (114K), phosphorylase B (97.4K), bovine serum albumin (66K), ovalbumin (45K), carbonic anhydrase (29K) and cytochrome *c* (12.5K).

Table 1 Comparison of the number of binding sites for PC61 antibody and IL-2 on activated B and T cells

Cell type (no. of experiments)	IL-2 binding sites			PC61 binding sites	Ratio PC61/IL-2 binding sites
	Total ($\times 10^{-3}$)	Ratio low/high	K_d (pM)	($\times 10^{-3}$)	
B blasts (3)	18 ± 3	10	23/1,150	40	2.2
T blasts (3)	37 ± 5	12	19/1,360	73	2.0
B1.8 (2)	29 ± 4	8	17/1,420	48	1.7
B6.1 (2)	79 ± 9	9	16/690	165	2.1
BD210 (3)	166 ± 14	14	25/1,800	285	1.7

Equilibrium binding of IL-2 and PC61 antibody was measured as described in Fig. 1 legend and the data processed by computer analysis. For each cell type we show the total number of IL-2 binding sites per cell, the ratio of the number of low- to high-affinity IL-2 binding sites per cell and the K_d of both classes of receptor (high/low affinity). The number of PC61 binding sites was also calculated by Scatchard analysis. The final column shows the ratio of the number of PC61 antibody binding sites to the total number of IL-2 binding sites per cell. The following IL-2-independent cell lines were found to be negative for specific binding of both IL-2 and PC61; Jurkat, EL4, BW5174, LSTRA, and mouse spleen and thymus cells. B and T blasts were prepared as described in Fig. 1 legend. B1.8 (ref. 20) is an antigen-dependent cytotoxic T lymphocyte (CTL) clone derived from a (Cremona × CD)F_1 mouse. B6.1 and BD2.10 are two antigen-independent CTL clones derived from C57BL/6 and (C57BL/6 × DBA)F_1 mice, respectively[21].

the K_d values that we find for the high-affinity IL-2 receptors and the absolute number of receptors of both classes (Table 1) agree closely with those of Robb *et al.*[11]; however, they report a 10–20-fold lower K_d (20–40 nM) for the low-affinity IL-2 receptors. Because we have found that the dissociation rate of IL-2 from the low-affinity receptors is very fast ($t_{1/2} \sim 45$ s at 4 °C in medium; our unpublished data), we believe that this discrepancy in the estimates of the K_d of the low-affinity receptors results from the additional washing steps in the protocol used in the previous study. Regardless of these technical considerations, it still remains to be established whether the low-affinity receptors are biologically functional or whether they are a recycled or degraded form of the high-affinity receptor.

Recently, we have characterized a rat monoclonal antibody, PC61 (ref. 10), which specifically recognizes the murine IL-2 receptor as shown by the fact that it (1) inhibits by 95% the IL-2-dependent proliferation of cloned cytolytic T cells; (2) binds specifically to IL-2-responsive cells; (3) inhibits by >90% (at either 4 °C or 37 °C) the binding of ^{3}H-IL-2 to both high- and low-affinity receptors; and (4) immunoprecipitates from surface-labelled activated T cells a band of similar relative molecular mass (M_r) to those reported for other anti-IL-2 receptor antibodies[4,5,16]. Figure 1*c* compares the equilibrium binding of ^{3}H-PC61 by LPS/anti-Ig-activated B blasts and Con A-activated T blasts; the binding is saturable and can be competed for by excess unlabelled PC61, and Scatchard analysis (Fig. 1*d*) reveals that both types of cell bind PC61 with equal affinity (K_d ~1 nM). At saturation, T blasts bind 73,000 molecules per cell, almost twice the number bound by B blasts, which is consistent with the IL-2 binding data. Our results are also in good agreement with the recent finding that rat and human T blasts bind, respectively, 75,000 and 100,000 anti-IL-2 receptor antibody molecules per cell[17,18].

To date, it has been difficult to reconcile estimates of the number of IL-2 receptors expressed per cell as measured by IL-2 binding, with those derived from binding of anti-receptor antibody. Table 1 compares quantitative IL-2 and PC61 binding to a variety of IL-2-dependent cells derived from different mouse strains. Even over an almost 10-fold range in total number of receptors per cell, the number of PC61 binding sites is about twice (1.7–2.2) the number of IL-2 binding sites. A similar finding for human cells has been published recently[11]; PHA-blasts and HUT-102 cells were found to have 2.0–2.6 times as many anti-

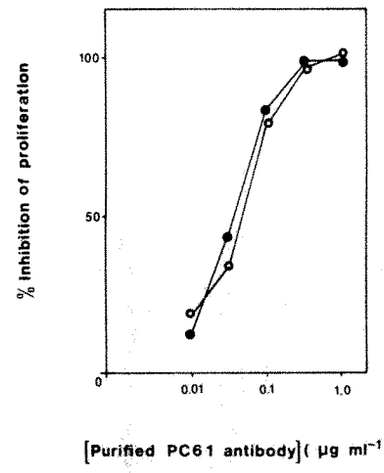

Fig. 3 PC61 antibody inhibits the IL-2-dependent proliferation of activated B and T cells. B blasts were prepared as described in Fig. 1 legend, collected on day 3, centrifuged on a Ficoll/Hypaque gradient and washed. 10^4 cells were cultured in 200 μl of RPMI-1640 medium containing 10% fetal calf serum (FCS). Cloned murine IL-2-dependent T cells (CTLL[28]) were washed three times and seeded at 4×10^3 cells per 200 μl of Dulbecco's modified Eagle's medium (DMEM) containing 5% FCS. To each well was added a suboptimal amount of IL-2 (giving 75% of maximum response in each assay) and various amounts of purified PC61 antibody. Cell proliferation was measured at 72 h (B blasts, ○) or 24 h (CTLL, ●) after a 6-h pulse with 1 μCi of ^{3}H-thymidine per well. A typical experiment is shown here, where symbols represent mean values of triplicate wells (s.e.m. = 10% of mean). Maximum c.p.m. in the absence of PC61 was 3.3×10^4 and 1.6×10^4 for B blasts and CTLLs, respectively. Thymidine incorporation, in the absence of added IL-2, was 500 c.p.m. for both populations. Similar results were obtained from 48-h cultures of CTLLs. From several experiments, the concentration of antibody giving 50% inhibition of proliferation was in the range 25–50 ng ml^{-1} for both cell types.

Tac[18] antibody binding sites as IL-2 binding sites. The reason for this difference is not clear, but a possible explanation is that two antibodies bind to a single IL-2 receptor. Alternatively, the difference could be explained by the binding of PC61 to molecules which do not bind IL-2 with a detectable affinity.

Flow microfluorometric analysis (Fig. 2*A*) shows that the distribution of PC61 antigen on LPS/anti-Ig-activated B blasts is similar to that seen on an IL-2-dependent cytolytic T-cell clone. Over 95% of the cells express the PC61 antigen. Analysis by SDS-polyacrylamide gel electrophoresis (PAGE) (Fig. 2*B*) reveals that the PC61 antigen immunoprecipitated from LPS/anti-Ig-activated B cells, T blasts or cloned T cells migrates as a broad band with an apparent M_r of 50,000–70,000 (50–70K) (reduced form) and 45–65K (non-reduced). This major band is similar to those reported by others using independently derived anti-IL-2 receptor antibodies[4,5,18,19]. In addition, three minor bands of lower M_r are consistently observed under reducing conditions; one at ~25K and two at 14–17K. The presence of low-M_r bands (20–25 K) has been reported previously for murine T cells[16]. The broad, high-M_r band precipitated from B blasts migrates slightly faster (reduced and non-reduced) than that of T cells and the low-M_r bands are less pronounced (Fig. 2*B*, lane *g*). We have also observed bands of similar M_r following precipitation with the 7D4 anti-IL-2 receptor antibody[4] (provided by Dr T. R. Malek). The heterogeneity in immunoprecipitation patterns observed between the different cell types studied (also reported for a variety of human T cells[19]), necessitates further biochemical analysis, such as peptide mapping, before the fine structure of the IL-2 receptors expressed by activated B and T cells can be compared.

Figure 3 shows that PC61 inhibits the IL-2-dependent proliferation of activated B and T cells at antibody concentrations very similar to those which inhibit the binding of IL-2 to its receptor (unpublished results).

Thus, by several independent criteria, the IL-2 receptors expressed by LPS/anti-Ig-activated B cells and activated T cells are similar. Quantitative ^{3}H-IL-2 binding reveals that B blasts, like a variety of independently derived activated T cells, express two classes of IL-2 binding sites; one has a high affinity for IL-2 and the other a 50–100-fold lower affinity. Binding to both classes can be inhibited by the same monoclonal antibody. The ratio of the number of low- to high-affinity sites per cell for B blasts (10) is within the range found for activated T cells (8–14). In addition, studies using antibody PC61 show that: (1) >95% of activated B and T cells express IL-2 receptors; (2) IL-2-dependent proliferation of both cell types is inhibited at similar antibody concentrations; and (3) bands of similar M_r are immunoprecipitated from activated T and B cells. On the basis of these results, we propose that IL-2 promotes the growth of appropriately stimulated B and T cells via a common mechanism.

We thank Marianne Van Laer for technical assistance, Pierre Zaech for fluorescence-activated cell sorting, Dr J.-C. Cerottini for helpful discussion, Dr Kendall Smith for providing the DMS-3 monoclonal antibodies and Dr Jeffery Atkinson for help with the computer analysis of the binding data. This work was supported in part by grants from the Swiss NSF (to R.H.Z. and M.N.).

γ-Interferon transcriptionally regulates an early-response gene containing homology to platelet proteins

Andrew D. Luster*, Jay C. Unkeless* & Jeffrey V. Ravetch†

Interferons are a family of proteins first identified by their ability to induce cellular resistance to infection by many viruses. In addition to the antiviral properties it shares with the α- and β-interferons, γ-interferon (IFN-γ), a lymphokine secreted by activated T cells, activates macrophages, stimulates B cells, increases fibroblast and endothelial cell resistance to many non-viral intracellular parasites and modulates cell-surface proteins central to immune cell regulation[1–13]. To identify molecules involved in the IFN-γ response and characterize their modulation, we have isolated genes that are induced following recombinant IFN-γ treatment of U937 cells, a histiocytic lymphoma cell line with monocytic characteristics[14,15]. We report here the molecular cloning and characterization of a gene regulated by rIFN-γ in U937 cells as well as in human mononuclear cells, fibroblasts and endothelial cells. Messenger RNA from this gene is induced within 30 min of rIFN-γ treatment and demonstrates maximal (>30-fold) accumulation within 5 h. Increased transcription is partly responsible for this accumulation. This gene encodes a protein of relative molecular mass (M_r) 12,378 which has significant amino-acid homology to platelet factor-4 and β-thromboglobulin, two chemotatic proteins released by platelets on degranulation. This IFN-γ-inducible protein may be a member of a family of proteins involved in the inflammatory process.

A complementary DNA library was constructed from poly(A)$^+$ RNA isolated from U937 cells treated with recombinant γ-interferon (18 h induction, 100 U ml^{-1}) and cloned into the *Pst*I site of pBR322 (refs 16, 17). Approximately 10,000 recombinants were screened for rIFN-γ-inducible sequences by differential colony hybridization using cDNAs prepared from rIFN-γ-induced and control poly(A)$^+$ RNAs. One cDNA clone, pIFNγ-31, showed a dramatic induction by Northern blot analysis and was chosen for further characterization.

rIFN-γ induces the accumulation of pIFNγ-31 mRNA in a dose-dependent manner. Figure 1*a* shows the accumulation of pIFNγ-31 mRNA in U937 cells in response to an 18-h incubation with various concentrations of rIFN-γ and rIFN-β. A detectable increase in pIFNγ-31 mRNA levels was seen at 10 U ml^{-1} rIFN-γ, with maximal accumulation at 100 U ml^{-1} rIFN-γ. pIFNγ-31 mRNA seems to be preferentially modulated by rIFN-γ; 100 times more antiviral units of rIFN-β than rIFN-γ were needed to produce a comparable effect (Fig. 1*a*, compare 10 U ml^{-1} rIFN-γ and 1,000 U ml^{-1} rIFN-β). Even at very high doses of rIFN-β (5,000 U ml^{-1}), the accumulation of pIFNγ-31 mRNA was only 40% of the maximal accumulation seen with 100 U ml^{-1} rIFN-γ. The submaximal stimulation of pIFNγ-31 mRNA by rIFN-β may result from cross-reactivity of this molecule with the IFN-γ receptor at very high IFN-β levels[18].

Figure 1*b* shows the kinetics of pIFNγ-31 mRNA accumulation at optimal rIFN-γ concentration (100 U ml^{-1}, see Fig. 1*a*). mRNA levels doubled within 30 min of induction and reached a maximal 34-fold increase within 5 h. By 18 h, half-maximal levels were observed, decreasing to a two-fold level by 34 h. In addition, 50 μg ml^{-1} of cycloheximide, which inhibited protein synthesis by >97%, did not inhibit the accumulation of pIFNγ-31 mRNA (data not shown). The rapidity with which pIFNγ-31 mRNA accumulates after rIFN-γ induction and its insensitivity to protein synthesis inhibitors suggest that this is a primary response gene in IFN-γ induction[19].

To determine whether IFN-γ affects transcription, the nuclear run-on transcription assay on isolated nuclei was used to measure the level of transcription of pIFNγ-31 mRNA in resting and rIFN-γ-treated cells. Figure 1*c* demonstrates that rIFN-γ increases the rate of transcription of pIFNγ-31 mRNA, thus establishing a role for γ-interferon in transcriptional activation. Recent studies[20,21] have demonstrated that the α/β-interferons can affect the transcription of several genes within minutes after the binding of interferon to its receptor. The analysis of an IFN-α-responsive gene from neuroblastoma cells suggests that IFN-α is also regulating post-transcriptional events[20].

To elucidate the function of pIFNγ-31, we determined the inducibility of this mRNA in different human cells. Figure 2 shows a panel of paired RNAs using various human cell lines, human peripheral blood mononuclear cells (PBM) and normal human spleen. To date, we have observed no primary cells which express this gene in the absence of rIFN-γ induction, in contrast

to DR-α and HLA-B7, two molecules shown to be induced by IFN-γ, which are constitutively expressed in many cells. pIFNγ-31 mRNA was preferentially induced in a primary human foreskin fibroblast after an 18-h incubation with 100 U ml^{-1} rIFN-γ. Human umbilical cord vein endothelial cells expressed pIFNγ-31 mRNA after incubation with rIFN-γ (100 U ml^{-1}, 12 h), but not rIFN-β (100 U ml^{-1}, 12 h) (data not shown). Figure 2 also demonstrates that pIFNγ-31 mRNA is induced in PBM and U937 cells within 5 h of treatment with 100 U ml^{-1} rIFN-γ, again in contrast to the regulation of DR-α and HLA-B7 mRNAs in

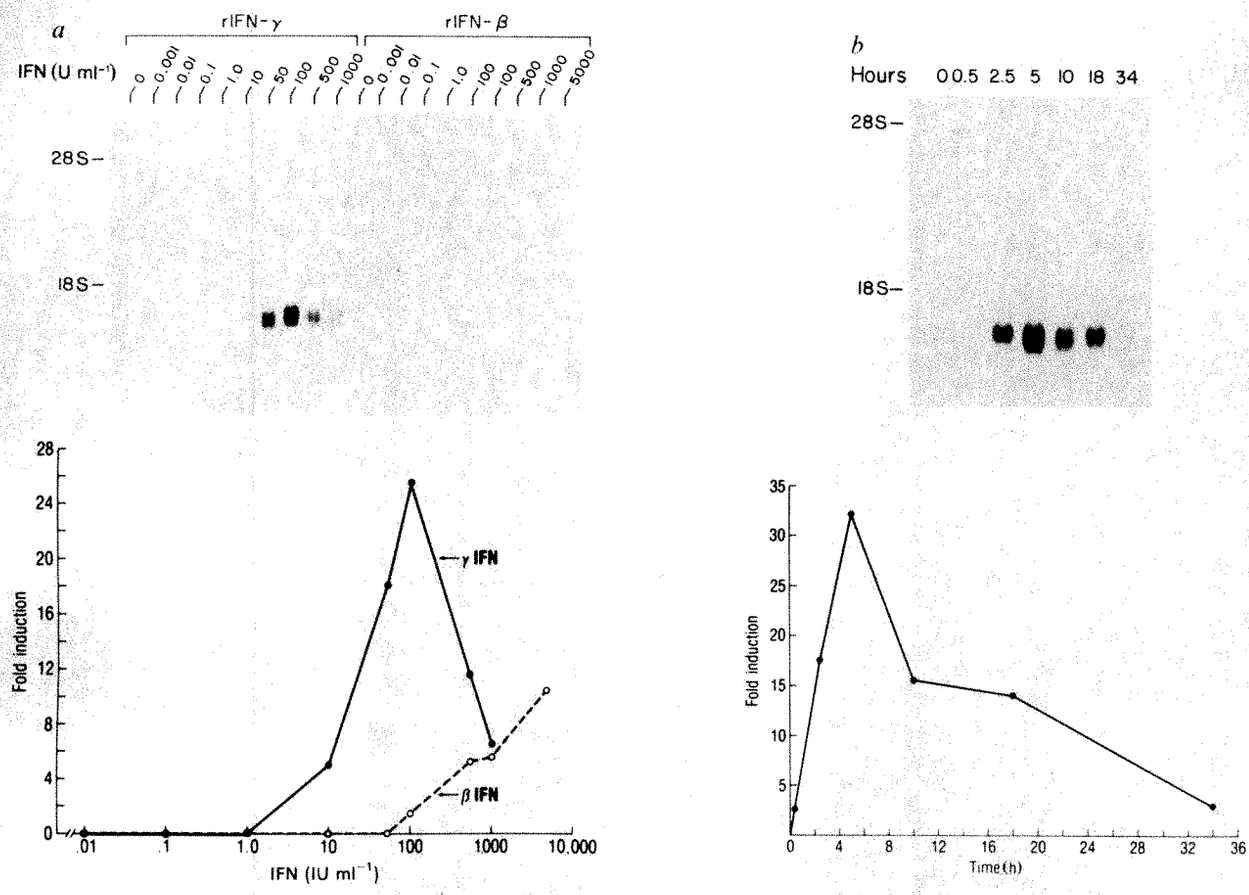

Fig. 1 Dose response, kinetics and transcription of pIFNγ-31 mRNA in response to IFN. *a*, Dose response of pIFNγ-31 mRNA accumulation in response to interferons; *b*, kinetics of accumulation; *c*, nuclear run-on transcriptional analysis. *a*, Top, autoradiogram of RNA blot analysis of the accumulation of pIFNγ-31 mRNA in U937 cells in response to 18-h incubations with various concentrations of rIFN-γ and rIFN-β. Bottom, quantitation of the RNA blot shown in the top panel by densitometer scanning (fold induction = densitometer units induced/densitometer units uninduced). *b*, Top, autoradiogram of the time course of pIFNγ-31 mRNA accumulation in U937 cells in response to 100 U ml^{-1} rIFN-γ, with quantitation shown in the bottom panel. 28S and 18S ribosomal RNA size markers are indicated in both upper panels. *c*, Plasmids containing the indicated genes were bound to nitrocellulose filters and hybridized with ^{32}P-labelled run-on transcripts from nuclei isolated at 3.5 h after addition of 100 U ml^{-1} rIFN-γ to U937 cells. To quantify the transcriptional induction, the hybridizing signals were excised and counted by liquid scintillation. The relative rates of transcription are expressed as parts per million (p.p.m.). p.p.m. = (c.p.m. sample − c.p.m. control)/total input c.p.m. C, Control (uninduced); γ, rIFN-γ induced.

Methods. *a*, *b*, The human histiocytic lymphoma cell line U937[14] was grown in RPMI-1640 supplemented with 10% fetal bovine serum. The recombinant interferons produced in *Escherichia coli* were generously provided by Hoffmann-La Roche. All the interferons were standardized by Hoffmann-La Roche using a cytopathic effect inhibition assay with vesicular stomatitis virus in WISH (HeLa) cells; activity was expressed in international antiviral units (U) per ml. The rIFN-γ lot used had a specific activity of 6.3×10^6 U mg^{-1} and the rIFN-β was clinical-grade material with a specific activity of 8×10^7 U mg^{-1}. The cells were induced with the interferons for this and all subsequent experiments at $2\text{–}5\times10^5$ cells ml^{-1}. RNA was isolated by the guanidine thiocyanate method[38] and 10 μg per line was fractionated on a 1% agarose/2.2 M formaldehyde gel and transferred to nitrocellulose as described elsewhere[39]. The filters were hybridized with ^{32}P-nick-translated pIFNγ-31.0 cDNA insert at a specific activity of $2\text{–}5\times10^8$ c.p.m. per μg, washed in stringent conditions (0.1 × SSC, 0.1% SDS, 52 °C), then subjected to autoradiography with Kodak XAR film using a Dupont Cronex intensifying screen at −70 °C for 2.5 h. *c*, RNA chain elongation in isolated nuclei was performed as described elsewhere[40], except that unincorporated nucleotide was removed by gel filtration of the purified nuclear RNA[41]. 10^8 nuclei were resuspended in 200 μl of incubation buffer containing 5 mM dithiothreitol, 5 mM $MgCl_2$, 90 mM KCl, 50% glycerol, 20 mM HEPES *p*H 7.6, 1 mM GTP, 1 mM CTP, 3 mM ATP, 250 μCi of ^{32}P-UTP, and incubated for 10 min at 37 °C. RNA purification was performed as described previously[40]; DNase I digestion was followed by deproteination with phenol, chloroform/isoamyl alcohol extractions, and concentration by ethanol precipitation. Approximately 2 μg of recombinant plasmid were linearized with *Bam*HI, boiled for 10 min, base denatured, neutralized and applied to 0.45-μm nitrocellulose filters[42] using a Minifold dot apparatus (Schleicher & Schuell). 6.9×10^6 c.p.m. ml^{-1} and 5.6×10^6 c.p.m. ml^{-1} of trichloroacetic acid-precipitable counts were used in rIFN-γ-induced and control hybridization reactions, respectively. Hybridization, RNase A and T_1 digestion, and washing of filters were performed as described previously[40]. The X-ray film was exposed at −70 °C with an intensifying screen for 4 days. The HLA-B7 cDNA plasmid was generously provided by S. Weissman[43].

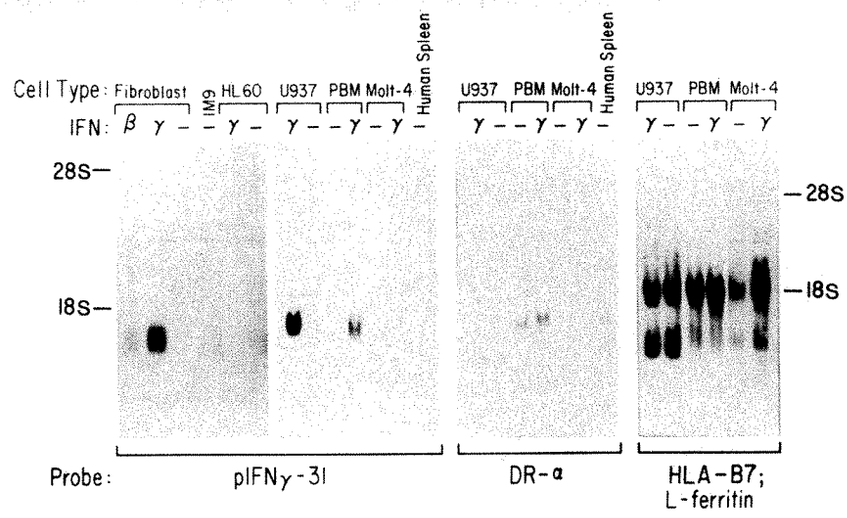

Fig. 2 Cell distribution and IFN-γ dependence of pIFNγ-31 mRNA accumulation. RNA blots were performed on the RNAs extracted from the indicated cells induced with rIFN-γ (γ) or induced with rIFN-β (β), or which received no treatment (−). Filters were hybridized with the probe indicated below the blots. **Methods.** RNA transfers contained U937, PBM, MOLT-4 and normal human spleen RNA. RNA (10 μg per lane) was fractionated; the 18S and 28S ribosomal RNAs are indicated on the far right. In the blot probed with HLA-B7 and L-ferritin, the HLA-B7 mRNA is the larger of the two transcripts. The far-left blot contains fibroblast, HL60 and IM9 RNA. In this blot, 2 μg of poly(A)$^+$ RNA was fractionated per lane; the 18S and 28S rRNA for this filter are indicated on the far left. U937 cells, PBM and MOLT-4 cells were induced with 100 U ml^{-1} rIFN-γ for 5 h. The fibroblasts and HL-60 cells were induced with 100 U ml^{-1} of both rIFN-β and rIFN-γ for 18 h. RNA isolation, RNA blot analysis and interferon induction were performed as indicated in Fig. 1 legend, except that the fibroblasts were confluent monolayers. The primary human foreskin fibroblast FS4 was obtained from S. Gupta and grown in minimum essential medium supplemented with 10% fetal calf serum (FCS). The cell lines HL60, IM9 and MOLT-4 were grown in RPMI-1640 supplemented with 10% FCS. Normal human peripheral blood was fractionated on a Ficoll–Hypaque gradient and the PBM were cultured in RPMI-1640 + 10% FCS. Normal human spleen was obtained from an incidental splenectomy and RNA was isolated by the guanidine thiocyanate method[38]. The HLA-DR α-chain cDNA plasmid was generously provided by J. Lee[44] and the human L-ferritin cDNA plasmid by M. H. Dorner[45].

PBM and U937 cells where, 5 h after rIFN-γ stimulation, no significant modulation in mRNA levels was detected. When cells from the human T-cell leukaemia cell line MOLT-4 were incubated for 18 h with 100 U ml^{-1} rIFN-γ, an increased accumulation of HLA-B7 mRNA was observed, but no expression of either DR-α mRNA or pIFNγ-31 mRNA. HL-60 cells, a promyelocytic leukaemia cell line, showed no induction of pIFNγ-31 mRNA after an 18-h incubation with 100 U ml^{-1} rIFN-γ. Induction of pIFNγ-31 mRNA by rIFN-γ in mononuclear cells, fibroblasts and endothelial cells indicates that this gene is induced in a diverse population of cells in response to IFN-γ.

The DNA sequence of pIFNγ-31 was obtained from two overlapping cDNA clones (Fig. 3*a*). Each base was sequenced from both strands using the dideoxy method of Sanger and Coulson[22] and the chemical cleavage method of Maxam and Gilbert[23]. The longest open reading frame begins at nucleotide 70, extending for 294 nucleotides before terminating at nucleotides 364–366 with TAA. pIFNγ-31 mRNA contains the classical polyadenylation signal AAUAAA, 12 bases from the start of the poly(A) tail (underlined in Fig. 3*a*). There is a long 811-base 3′-untranslated region, a 294-nucleotide coding region and a ~220-nucleotide 5′-untranslated region.

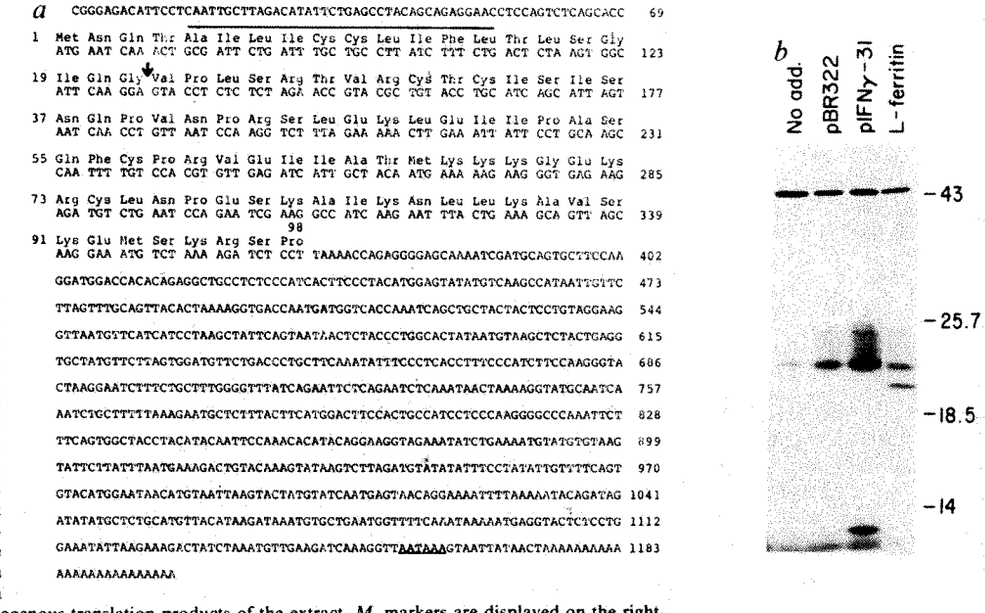

Fig. 3 Primary structural analysis of pIFNγ-31 cDNA clones. *a*, Determined nucleotide sequence and predicted amino-acid sequence of pIFNγ-31; *b*, hybridization selection and translation of pIFNγ-31 mRNA. The coding strand is displayed in *a*; the number of the nucleotide residue at the right end of each line is given. The polyadenylation signal is underlined. The deduced amino-acid sequence is shown above the nucleotide sequence, numbered beginning with the putative initiating methionine. The hydrophobic core of the predicted signal sequence is overlined and the predicted signal peptidase cleavage site is indicated by an arrow. Hybridization selection and translation of pIFNγ-31 mRNA (*b*) were performed to confirm the open reading frame predicted above. Poly(A)$^+$ mRNA from U937 cells induced by 5 h treatment with rIFN-γ (100 U ml^{-1}) was annealed to nitrocellulose filters containing pIFNγ-31 and control clones pBR322 and L-ferritin. The mRNA was eluted and translated *in vitro* using a rabbit reticulocyte lysate extract and ^{35}S-methionine label. An autoradiogram of the translation products fractionated on a 12.5% SDS-polyacrylamide gel is shown in *b*. The 'no add.' lane shows only the endogenous translation products of the extract. M_r markers are displayed on the right. **Methods.** *a*, DNA sequence analysis was performed using the dideoxy method of Sanger and Coulson[22] and the chemical cleavage method of Maxam and Gilbert[23]. The entire coding region of pIFNγ-31 consisted of two overlapping cDNAs. pIFNγ-31.0 was isolated in the differential colony hybridization screening, extended from nucleotides 451 to 1,198, and used to rescreen a size-fractionated cDNA library. 10,000 recombinants were screened with an *Eco*RI/*Pvu*III fragment of pIFNγ-31.0. Seven colonies hybridizing to this probe were picked, rescreened, then analysed by restriction mapping. One clone, pIFNγ-31.7, contained the most 5′-nucleotide sequences and extended from nucleotides 1 to 875. *b*, Hybridization selection of specific mRNAs was performed essentially as described previously[46]. Plasmid DNA (10 μg) were linearized and bound to 0.45-μm nitrocellulose filters as indicated in Fig. 1 legend. Hybridization was carried out at 50 °C for 3 h in a 250-μl volume containing 65% formamide, 20 mM PIPES (*p*H 6.4), 0.1% SDS, 0.4 M NaCl, 50 μg yeast transfer RNA and 45 μg poly(A)$^+$ RNA. Filters were then washed six times with 50 ml of 0.15 M NaCl, 0.01 M Tris *p*H 7.6, 1 mM EDTA, 0.5% SDS at 65 °C. The filters were washed twice more with 50 ml 0.15 M NaCl, 0.01 M Tris *p*H 7.6, 1 mM EDTA at 65 °C. Selected RNAs were eluted by boiling in 300 μl of H_2O for 60 s and then quickly freezing in a dry-ice ethanol bath. The eluted RNAs were extracted with $CHCl_3$/phenol and then ethanol precipitated in 0.25 M sodium acetate with 20 μg yeast tRNA as a carrier. The pellets were washed once with 70% ethanol and dissolved in 5 μl H_2O. Each selected RNA (1 μl) was used to program an Amersham RRL *in vitro* translation system using ^{35}S-methionine as label.

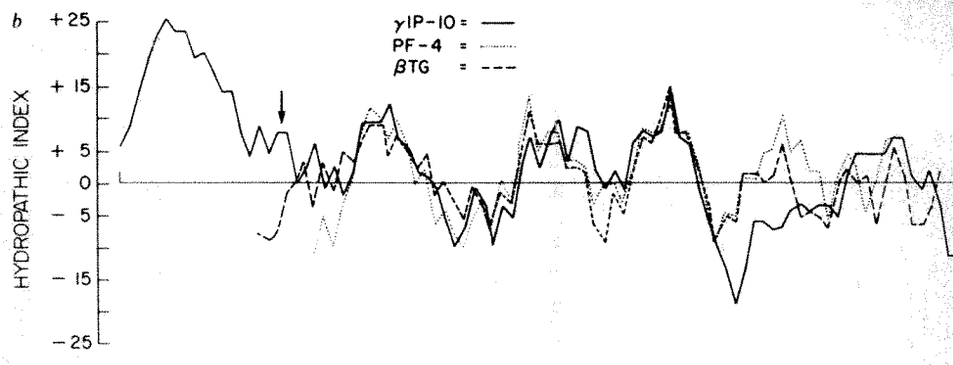

Fig. 4 *a*, Amino-acid homology between γIP-10, PF-4-human (PF-4), PF-4-bovine (PF4 30) and β-TG-human (βTG-Hu). The optimized amino-acid alignment, which includes gaps, was done by implementing a Needleman–Wunsch algorithm[47] over the initial dfastp alignment. The one-letter amino-acid notation is used. A colon indicates an exact match, a period a 'conservative mutation' (can be obtained with only one DNA base change) and a blank a 'non-conservative mutation' (at least two DNA bases would have to be changed). *b*, Hydropathy profile of γIP-10 (——), PF4-Hu (···) and βTG-Hu (---). The hydropathic value of each amino acid was determined by using the scoring system of Kyte and Doolittle[48]. The average hydropathic value at residue i is calculated across seven residues from $i-3$ up to and including $i+3$. Positive values indicate hydrophobic regions and negative values hydrophilic segments. Each protein was plotted independently and overlaid to obtain the composite seen above. The hydropathic value of each amino-acid residue is plotted from the amino terminus to the carboxyl terminus (left to right along the abscissa). The entire coding region of γIP-10 is plotted, but only the mature PF-4 and β-TG proteins are plotted. The arrow indicates the predicted signal peptide cleavage site of γIP-10.

The deduced amino-acid sequence (Fig. 3*a*) beginning with the initiation codon AUG at nucleotides 70–72 encodes a protein of 98 amino acids and predicts a protein of M_r 12,378, termed γIP-10. The highly hydrophobic stretch of 10 amino acids (residues 5–14 overlined in Fig. 3*a*) is typical of the hydrophobic core of a signal peptide[24]. Application of the empirical rules proposed by Von Heijne[25] predicts the signal peptidase cleavage site to be after residue 21 (Gly, arrow Fig. 3*a*). Analysis of the amino-acid sequence reveals no other hydrophobic regions which could serve as a transmembrane region and anchor the protein in the membrane. This suggests that the protein is secreted and that the unmodified mature protein has a M_r of 9,979. Consistent with γIP-10 containing a signal peptide, its mRNA is enriched in the microsomal fraction (data not shown). The predicted amino-acid sequence for γIP-10 contains no *N*-linked glycosylation sites (Asn-X-Thr/Ser).

Hybridization selection and translation of pIFNγ-31 were performed to confirm the predicted open reading frame. Poly(A)$^+$ mRNA from U937 cells treated for 5 h with rIFN-γ was annealed to nitrocellulose filters containing pIFNγ-31 and control clones (L-ferritin and pBR322) and then eluted. The selected mRNA was translated using a rabbit reticulocyte lysate with ^{35}S-methionine label and fractionated on a 12.5% SDS-polyacrylamide gel (Fig. 3*b*). mRNA from clone pIFNγ-31 directs the synthesis of a ~12,000-M_r protein which is not present in the control lanes, confirming the existence of an mRNA which can direct the synthesis of the γIP-10 protein in rIFN-γ-induced U937 cells.

Using the program 'dfastp' (ref. 26), we searched the National Biomedical Research Foundation Library for any protein containing homology to the predicted amino-acid sequence for γIP-10. Two proteins, platelet factor-4 (PF-4) and β-thromboglobulin (β-TG), have significant homology to the predicted amino-acid sequence of γIP-10. Alignment of these three sequences is shown in Fig. 4*a*. γIP-10, PF-4 and β-TG demonstrate 35% identity in a 62-amino-acid overlap. β-TG has been reported to contain two disulphide bonds linking residues 16–42 and 18–58 (ref. 27). When PF-4, β-TG and γIP-10 were aligned for maximum homology (Fig. 4*a*), the cysteine residues of the mature proteins were perfectly aligned, suggesting preservation of tertiary structure among these molecules. Consistent with this notion is the similarity in the hydropathy profile of the proteins (Fig. 4*b*); there is a striking conservation of hydrophobic (peaks) and hydrophilic (troughs) domains between the three proteins. The hydrophobic core of the predicted leader peptide of γIP-10 is clearly evident with the predicted signal peptidase cleavage site indicated by an arrow in Fig. 4*b*.

PF-4 and β-TG proteins are stored in the α granule of platelets and secreted concomitantly during the platelet-release reaction[28]. Although the *in vivo* functions of PF-4 and β-TG remain unclear, *in vitro* studies suggest that these proteins are important mediators of inflammation and wound healing[29–37]. The homology between γIP-10, PF-4 and β-TG suggests that γIP-10 may also be involved in the inflammatory response. The rapid and specific induction of pIFNγ-31 mRNA by IFN-γ in a diverse population of cells suggests that γIP-10 may be central to the IFN-γ response. The role for this family of related polypeptides in inflammation and immune cell regulation as well as the molecular characterization of transcriptional activation by IFN-γ are under investigation.

We thank Drs John Moshera, R. Patrick Gage and Patrick Trown (Hoffmann-La Roche) for their generous gift of recombinant interferons. We also thank Amalia Pavlovec for technical help, Drs Michael Sheffery and Roger Cohen for their help with the nuclear-run off assay, Dr Nicholas A. Pawlowski for the purified endothelial cells, and Karen Yates and Mary Wentzler for secretarial assistance. This work was supported in part by grants to J.V.R. from the NSF (PCM-8409225), the Kleberg Foundation, the Charles E. Culpeper Foundation and CA-08748, and to J.C.U. from the NIH (AI 14603). A.D.L. is supported by the NIH MSTP grant to the Cornell-Rockefeller MD/PhD programme.

Insulin receptor tyrosine kinase is defective in skeletal muscle of insulin-resistant obese mice

Yannick Le Marchand-Brustel, Thierry Grémeaux, Robert Ballotti & Emmanuel Van Obberghen

Unité de Recherches sur les Hormones Polypeptidiques et la Physiopathologie Endocrinienne, INSERM U 145, Chemin de Vallombrose, 06034 Nice Cedex, France

Obese syndromes of genetic origin or experimentally induced are characterized by resistance to insulin both *in vivo* (association of hyperglycaemia and hyperinsulinaemia) and *in vitro*[1]. Thus, skeletal muscle of obese mice, which is the most important target organ for the action of insulin, displays a reduced response to insulin[2–4]. This hormonal resistance cannot be explained by the moderate decrease in the number of insulin receptors found in obese animals[3–5]. In fact, it is generally believed that a biochemical event occurring very early after binding of insulin to its receptor, which is the first step in insulin action, is defective in obesity. One of the earliest post-binding events so far recognized, and which is thought to have a key role in cellular signalling by the insulin receptor, is the insulin-stimulated phosphorylation of its receptor[6–8]. In an effort to localize the defect responsible for the insulin resistance in obesity, we have studied the insulin receptor protein kinase activity and we show here that insulin receptors from skeletal muscles of insulin-resistant obese mice have an altered kinase activity for phosphorylation of both the receptor itself and of exogeneous substrates.

The animals used in the present study were male Swiss albino mice. Mice were rendered obese with a double injection of gold thioglucose at 3 weeks of age and they were used at 25–30 weeks when obesity was fully expressed[3,4]. Lean controls were age- and sex-matched animals. All animals were fed *ad libitum* on a standard diet until the time of killing. Following gold thioglucose injection, which induces hyperphagia, mice became markedly obese (Table 1). They were hyperglycaemic and insulin-resistant since insulin induced *in vivo* a poor hypoglycaemic effect. Using wheat-germ lectin chromatography, partially purified insulin receptors were prepared from skeletal muscle of lean and obese mice, and they were then used in a cell-free phosphorylation assay as described previously[7–9]. For all tissues studied so far, insulin enhances several-fold the phosphorylation of its receptor β-subunit (relative molecular mass, M_r, 95,000); the other receptor subunit, termed α-subunit (M_r 130,000) and containing the insulin binding site, is generally not phosphorylated[10]. Similar results were found with receptors derived from rat skeletal muscle[11]. With insulin receptors obtained from skeletal muscle of lean mice, insulin markedly stimulated the phosphorylation of a polypeptide of M_r 95,000 (Fig. 1); this phosphoprotein corresponds to the β-subunit of the insulin receptor, as it was immunoprecipitated by a highly specific antiserum[12] to insulin receptor (lanes *d*, *h*), but not by normal serum (lanes *c*, *g*). More importantly, the effect of insulin on phosphorylation of its receptor was less pronounced in the preparation from insulin-resistant obese mice (lane *h*) compared with lean controls (lane *d*). The decreased insulin effect observed in obese mice is unlikely to result from a residual occupation of insulin receptors due to the high levels of circulating insulin in obese mice (Table 1), as basal phosphorylation was negligible in both groups of mice (lanes *b*, *f*).

Table 1 Characteristics of mice used (*a*) and binding capacity of partially purified insulin receptor preparations (*b*)

a	Lean	Obese
Body weight (g)	43.4 ± 1.2	66.5 ± 3.5
Blood glucose (mg per 100 ml)		
Before insulin	162 ± 8	334 ± 27
30 min after insulin	61 ± 4	294 ± 37
Insulinaemia (ng ml^{-1})	3.2 ± 0.7	50.8 ± 11.1
	Specific binding of ^{125}I-insulin	
b	Lean	Obese
Soleus muscles (per cent per mg protein)	0.52 ± 0.04	0.37 ± 0.03
Partially purified receptors (per cent per μg protein)	3.81 ± 0.21	2.94 ± 0.22

Mice were injected with gold thioglucose at 3 weeks of age and used at 25–30 weeks[3,4]. Insulin resistance was tested *in vivo* by measuring plasma glucose before and after an intravenous insulin injection (0.5 U per kg body weight). Insulin binding was measured in soleus muscles as described previously[3] or in partially purified insulin receptors: 10 μl of partially purified receptor preparations was incubated in HEPES (50 mM), NaCl (150 mM) buffer *p*H 7.6 containing ^{125}I-labelled insulin (10^{-11} M) in the absence or presence of unlabelled insulin (10^{-6} M) in a final volume of 200 μl. After 2 h at 20 °C, bound insulin was separated from unbound hormone using polyethylene glycol. Nonspecific binding represented 10–15% of total binding. Values are the mean ±s.e.m. of five measurements for insulin test, eight for soleus muscles or six for partially purified receptor preparations.

Insulin binding was decreased only to a moderate extent (~30%) in intact soleus muscles[3] from obese mice compared with controls, and a similar moderate defect (22%) in insulin binding was observed using partially purified insulin receptors from obese animals (Table 1). Scatchard analysis of the insulin binding data revealed that this was due only to a decrease in receptor number without any change of binding affinity (data not shown). The altered autophosphorylation of insulin receptors from skeletal muscle of obese mice could be due to a decreased number of receptors or, alternatively, due to an intrinsic defect of the insulin receptor kinase in obese mice. To approach this question, we next studied insulin receptors from skeletal muscle of lean and obese mice for self-phosphorylation of the receptor β-subunits present in identical amounts of receptors, as measured by Scatchard analysis and affinity labelling of α-subunits with ^{125}I-insulin. Partially purified insulin receptors were incubated with ^{125}I-photoreactive insulin followed by ultraviolet irradiation for covalent affinity labelling of insulin receptors. SDS-polyacrylamide gel electrophoresis (SDS-PAGE) revealed the presence of a major labelled polypeptide with M_r 130,000, which we recognize as the insulin receptor

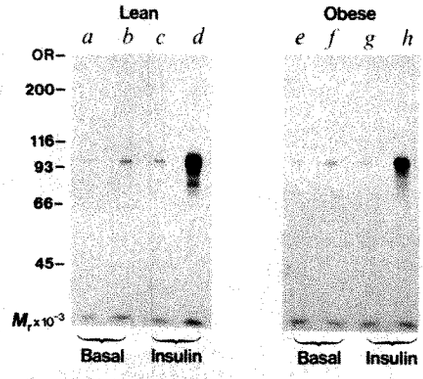

Fig. 1 Phosphorylation of skeletal muscle insulin receptors from lean and insulin-resistant obese mice. Skeletal muscles were obtained from the hindlegs of 30-week-old normal Swiss mice (lean) or mice injected with gold thioglucose (obese). Muscles (3 g) were homogenized (15 s, Polytron homogenizer, 2,000 r.p.m.) in 3 vol. HEPES (50 mM, *p*H 7.6), NaCl (150 mM), bacitracin (1 mM), aprotinin (1,000 trypsin-inhibitor units per ml), phenylmethylsulphonyl fluoride (1 mM) and Triton X-100 (1%). The homogenates were solubilized for 90 min at 4 °C by continuous stirring, and centrifuged at 150,000*g* at 4 °C for 90 min. The supernatants were applied to a wheat-germ-agglutinin-agarose column; after washing, bound glycoproteins were desorbed with 0.45 M *N*-acetylglucosamine[9]. Preparations from lean and obese mice were always performed in parallel. Partially purified insulin receptors were incubated in a reaction mixture containing HEPES (50 mM, *p*H 7.6), NaCl (150 mM) without (basal) or with 0.1 μM insulin at 15 °C for 90 min. Thereafter, the phosphorylation reaction was initiated adding [γ-^{32}P]ATP (15 μM), $MnCl_2$ (4 mM) and $MgCl_2$ (8 mM). After 30 min at 20 °C, the reaction was stopped by adding ice-cold stopping solution containing NaF (80 mM) and EDTA (30 mM). Insulin receptors were specifically immunoprecipitated with antiserum containing autoantibodies to the insulin receptor[12] (serum from patient B2 at a 1:300 dilution) (lanes *b, d, f, h*) or normal serum (lanes *a, c, e, g*) after a preclearing step with normal serum. The immunoprecipitates were boiled for 5 min in a solution containing SDS (3%, w/v), glycerol (10%, v/v), sodium phosphate (10 mM), 2-mercaptoethanol (5%) and bromophenol blue (0.05%) and subjected to one-dimensional SDS-PAGE with a 7.5% acrylamide resolving gel[21]. An autoradiograph of the gel is shown.

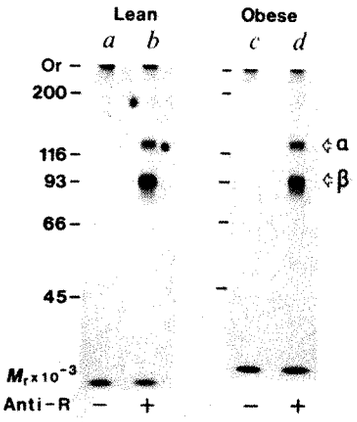

Fig. 2 Double labelling of α- and β-subunits of insulin receptors in lean and insulin-resistant obese mice. Partially purified insulin receptors were prepared from lean and obese mice as described in Fig. 1 legend. The amount of insulin receptors in the two preparations was determined by Scatchard analysis of insulin binding data; obese mice showed a reduction of 20% compared with lean mice (there was no change in insulin binding affinity). Identical amounts of receptors from lean and obese mice were first incubated with 5 nM ^{125}I-labelled photoreactive insulin (B29 (2-nitro,4-azido)phenylacetyl insulin) for 2 h at 15 °C in the dark; samples were then irradiated for 5 min at 4 °C using a high-pressure mercury lamp (Philips HPK; 125 W h^{-1}) as previously described[22]. Using this procedure, 20% of photoreactive ^{125}I-insulin was covalently linked to solubilized receptors after ultraviolet irradiation. At the end of photoactivation, phosphorylation was carried out as detailed in Fig. 1 legend. The labelled insulin receptors were then exposed to normal serum (lanes *a* and *c*) or anti-receptor serum B2 (lanes *b* and *d*), and the immunoprecipitates were subjected to SDS-PAGE under reducing conditions. An autoradiogram of the gel is shown.

α-subunit for the following reasons. First, the radioactive band with M_r 130,000 was not found when unlabelled insulin (10^{-7} M) was present together with ^{125}I-photoreactive insulin during the binding step. Second, the 130,000-M_r polypeptide was immunoprecipitable by anti-insulin antiserum and anti-receptor antiserum, but not by normal serum (data not shown). Based on estimates derived from Scatchard analysis of insulin binding, we took identical amounts of insulin receptors partially purified from skeletal muscle of lean mice and from insulin-resistant obese mice, respectively. Then, ^{125}I-photoreactive insulin was first covalently attached to the two receptor preparations, and the receptors were used in a cell-free phosphorylation assay as described previously. Finally, insulin receptors were specifically immunoprecipitated with antibodies to insulin receptor. The autoradiogram in Fig. 2 clearly shows that for an equal amount of insulin binding, as reflected by the identical labelling intensity of the receptor α-subunit, a much lower degree of phosphorylation of the insulin receptor β-subunit is found in partially purified receptors obtained from obese mice compared with lean mice. Thus, when the radioactivity present in the insulin receptor α- and β-subunits was measured by scanning densitometry in three different experiments, and the ratio of labelling of the β-subunit over the α-subunit was calculated, we found 2.9 ± 0.3 in lean mice, and 1.7 ± 0.2 in obese mice (mean ± s.e.m. of three experiments, each performed with a different insulin receptor preparation). This result indicates that in obese mice there is a marked alteration in the insulin-induced phosphorylation of the insulin receptor.

To evaluate further the possible role of a defect in insulin receptor kinase activity in the resistance to insulin seen in obesity, the ability of insulin receptors to catalyse the phosphorylation of exogenous substrates was investigated. The substrate used here was a copolymer of glutamate and tyrosine residues in a 4:1 ratio, which has been shown to be an excellent substrate for the insulin receptor protein kinase[13]. Insulin binding to the partially purified insulin receptors obtained from skeletal muscle of obese mice and used in these experiments was only decreased by 15% compared with lean mice. In contrast, phosphorylation of the substrate by partially purified insulin receptors from obese mice was decreased by 40% at all insulin concentrations compared with lean mice (Fig. 3). For both preparations, a half-maximal effect was obtained with 8×10^{-8} M insulin.

In our attempts to test the putative causal association between insulin resistance and loss of receptor kinase activity, we have investigated whether both defects evolve concomitantly in mice rendered obese. The insulin receptor tyrosine kinase activity of skeletal muscle was thus evaluated in young obese mice, which are not insulin-resistant, as they are hyperinsulinaemic and slightly hypoglycaemic, and they normally respond to exogenous insulin[4]. These 10-week-old non-insulin-resistant obese mice were compared with 30-week-old obese animals, which have developed an overt resistance to insulin. For both groups of obese mice, insulin binding to partially purified skeletal muscle insulin receptors was ~80% of the binding in the corresponding age-matched lean animals. In skeletal muscle from 10-week-old obese mice, the insulin-stimulated receptor tyrosine kinase activity towards an exogenous substrate was reduced in direct proportion to the decrease in insulin binding, that is, a reduction of approximately 20%. This is in striking contrast to the situation observed in 30-week-old insulin-resistant obese mice, where the diminution in receptor kinase activity (45%) is much more pronounced than would have been expected from the decrease in insulin binding (20%). Thus, in obesity with the development of insulin resistance and without any further change in insulin receptor number, a defect intrinsic to the insulin receptor tyrosine kinase activity appears.

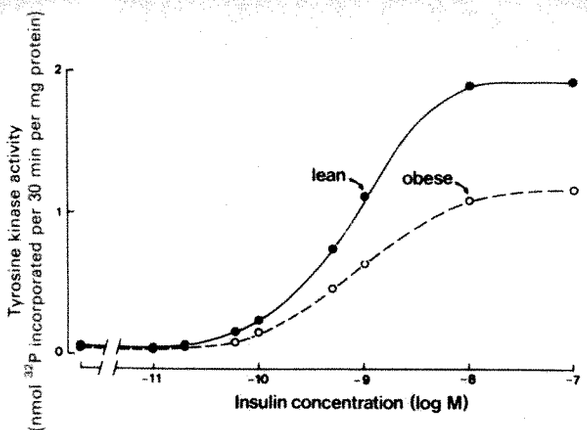

Fig. 3 Kinase activity of insulin receptors from lean and insulin-resistant obese mice towards an exogeneous substrate. Partially purified insulin receptors (25 μl), prepared from lean and obese mice as described in Fig. 1 legend, were preincubated in HEPES (50 mM), NaCl (150 mM), bovine serum albumin (0.2 mg ml^{-1}) buffer, *p*H 7.6 (final volume 140 μl) without or with various concentrations of insulin for 60 min at 24 °C. The substrate[13] (copolymer of glutamate/tyrosine, 4 : 1, 0.25 mg ml^{-1}) was then added for an additional 30 min. The phosphorylation reaction was initiated by adding 20 μl of a solution containing [γ-^{32}P]ATP, $MnCl_2$ and $MgCl_2$ at final concentrations of 20 μM, 3,000 c.p.m. pmol^{-1}, 4 mM and 8 mM, respectively. After 30 min the reaction was stopped by applying 75-μl samples to filter papers (Whatman ET31) and soaking the papers in a bath of 10% trichloroacetic acid (TCA), 10 mM sodium phosphate. After extensive washing in 5% TCA, radioactivity of the TCA-precipitable material was measured using Cerenkov radiation. Results are expressed as nmol of phosphate incorporated per mg receptor protein per 30 min.

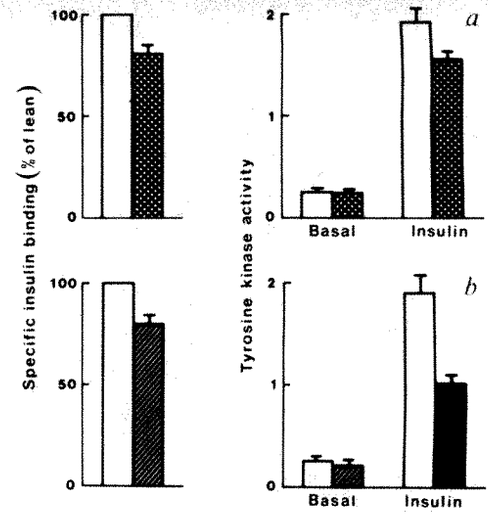

Fig. 4 A defect in insulin receptor tyrosine kinase activity appears with insulin resistance in skeletal muscle from obese mice. Insulin receptors were partially purified from skeletal muscle obtained from the following two groups of lean (open bars) and obese (shaded bars) mice: *a*, mice were aged 10 weeks, and the obese animals were not insulin-resistant (body weight (g) 35.9 ± 0.3 and 45.1 ± 1.0; blood glucose (mg per 100 ml) 217 ± 6 and 182 ± 6; insulinaemia (ng ml^{-1}) 1.9 ± 0.4 and 7.7 ± 1.8 for lean and obese mice, respectively; values are mean ± s.e.m. of 8–12 values; all differences were statistically significant with $P < 0.01$. *b*, Mice were 30 weeks old and the obese animals were insulin-resistant as described in Table 1. Insulin binding was measured in partially purified insulin receptors as described in Table 1, and the results are expressed as a percentage of the binding obtained in preparations from lean mice. Insulin receptor tyrosine kinase activity towards an exogenous substrate was measured in the absence (basal) or presence of insulin (10^{-7} M) as described in Fig. 3 legend and is expressed in nmol ^{32}P incorporated per mg receptor protein per 30 min. Values are the mean of five experiments, each performed with a different insulin receptor preparation.

Here we have presented evidence that the insulin receptor tyrosine kinase activity is markedly impaired in skeletal muscle of insulin-resistant obese mice. This defect in the enzyme function of the receptor was observed for both receptor autophosphorylation and the ability of the receptor to catalyse the phosphorylation of a synthetic substrate. This result indicates that the insulin-resistant state accompanying obesity can be related to an impaired activity of the insulin receptor kinase. Similarly, it has also been shown recently that the insulin resistance, which occurs in streptozotocin-diabetic rats, is accompanied by a decreased kinase activity of liver insulin receptors[14]. Our finding represents the earliest post-receptor binding alteration recognized so far in animal obesity, in which the insulin resistance is generally accepted to result mainly from a post-receptor defect. This observation may have important implications for our understanding of the insulin resistance commonly found in human obesity, which is the most frequent cause of hormone resistance in humans. Our model of animal obesity has a major feature in common with human obesity in that it is acquired. It thus excludes the possibility that the insulin receptor kinase activity is deficient due to the result of a genetic abnormality of the enzyme as it appears to occur in two recently reported cases of insulin resistance in extremely rare patients[15,16]. The alteration of intrinsic insulin receptor kinase activity in our obese animals could result from the chronic hyperinsulinaemia present in obese mice which induces a desensitized state of the receptor-associated enzyme function. Along this line, it has been suggested that diet-induced alterations of insulin receptor kinase activity could be related to different nutritional states or ambient plasma insulin levels in fasted and fasted, re-fed animals[17]. Our observations are similar to those of Carlin *et al.*[18] who show that senescent fibroblasts, which are resistant to epidermal growth factor (EGF) action, have a defect in their EGF receptor kinase despite an unchanged number of EGF receptors. Alternatively, the defective insulin receptor kinase activity found in obese mice could be due to inadequate coupling between the two insulin receptor subunits. The mechanism of signal transfer from the insulin binding subunit (α) to the β-subunit, responsible for the kinase activity, is unknown. It could be envisaged that this signal transfer is hampered in insulin-resistant obese mice. In contrast, a quantitative defect of solely the insulin receptor β-subunit in obese mice is very unlikely. Indeed, insulin-induced receptor loss (a phenomenon known as down-regulation[19]) leads to an identical decrease in both insulin receptor subunits[20]. Along the same line, the insulin receptor of obese mice could have a greater proportion of nicked β-subunits than lean mice. However, a careful analysis of our gels does not favour this contention.

It is generally believed that protein phosphorylation is an important mechanism by which a variety of extracellular stimuli regulate cellular functions. For the insulin receptor, the hormone-stimulated phosphorylation of its receptor is a very early post-binding event, and a fundamental property of the receptor as it occurs in all tissues studied thus far. The demonstration of an altered insulin-stimulated kinase associated with the insulin receptor activity in muscles of obese mice, which display insulin resistance for a variety of parameters (glucose transport and metabolism, glycogen synthase activation and amino-acid transport), argues strongly for a key role of receptor phosphorylation in insulin action.

Autoantibodies to the insulin receptor were given by Drs P. Gorden and C. R. Kahn and photoreactive insulin was given by Dr D. Brandenburg. We thank G. Visciano for illustration work and Mrs J. Duch, L. Capolongo and A. Rainaud for secretarial assistance, This research was supported by INSERM grant CRL 82.4.027.

Novel preparation for studying excitation–secretion coupling in the isolated single cell

P. G. Jones, R. T. Sawyer* & M. S. Berry

Department of Zoology, University College of Swansea, Singleton Park, Swansea SA2 8PP, UK

Cellular mechanisms of secretion in exocrine and endocrine glands are technically difficult to study. We present here a model which offers fundamental advantages for studying excitation–secretion coupling at the level of the isolated single cell. The salivary gland of the leech *Haementeria ghilianii* possesses a unique combination of unusual properties which greatly facilitate research in this area. Its cells are exceptionally large (up to 1 mm in diameter), clearly visible and easy to penetrate with microelectrodes. They do not form a homogeneous population but consist of five distinct histochemical types, secreting a number of identified products such as the fibrinolytic enzyme hementin (for which there is a sensitive assay). The cells generate overshooting calcium-dependent action potentials up to 90 mV in amplitude and with a duration of 200–1,000 ms. One of their most useful and unusual features is a lack of electrical coupling which means that individual cells can be studied in an intact gland without interference from neighbouring cells.

H. ghilianii is the world's largest leech (up to 0.5 m long) and was known only from two nineteenth-century reports until it was rediscovered by one of us in swamps in French Guyana[1]. Unlike most other leeches (for example, *Hirudo medicinalis*) in which the salivary cells are relatively small and scattered throughout the head musculature[2], those of *H. ghilianii* are very large and form a discrete gland containing ~240 cells (Fig. 1). Intracellular injection of Lucifer yellow indicates that the cells are not coupled because the dye does not pass into neighbouring cells[3].

Leech salivary glands contain a number of medically interesting peptides, including an anti-elastase, a vasodilator, hyaluronidase, an anti-metastasis factor, a possible local anaesthetic and a species-specific range of anticoagulants[4,5]. For example, the anticoagulant of *H. ghilianii* is hementin, an enzyme that specifically cleaves fibrinogen/fibrin[6].

These properties, together with the electrophysiological experiments reported here, suggest that the gland is a valuable model for glandular secretion, particularly because much is known about the biochemistry and mechanisms of action of some of the biologically active secretions mentioned above[5]. Features of the electrophysiology of this gland have recently been examined by Marshall and Lent[7]. Here we present the results of parallel studies and summarize the evidence which has led us to recognize the potential of this system as a gland model.

* Present address: Biopharm (UK) Ltd, PO Box 5, Swansea SA1 2ET, UK.

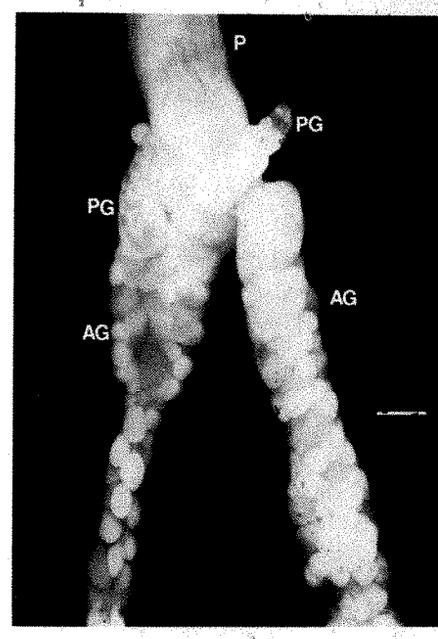

Fig. 1 Dissected salivary gland complex of *H. ghilianii*. P, proboscis; AG, anterior gland; PG, posterior gland. Cells, ranging up to 1 mm or more in diameter, are clearly visible for microelectrode penetration. Scale bar, 1 mm.

Dissected salivary glands were pinned to the base of a small Perspex bath and immersed in physiological saline[8]. Individual cells were impaled with two independent KCl-filled microelectrodes of 10–20 MΩ resistance; one electrode was used for recording potential and the other for passing current. Experiments were performed at room temperature (18–22 °C).

Resting potentials of between −35 and −80 mV were recorded, with no sign of spontaneous impulse activity or subthreshold potentials. Depolarizing pulses elicited overshooting action potentials which exceeded 90 mV in some cells. Action potentials were characterized by a shoulder on the repolarizing phase, pronounced after hyperpolarization (Fig. 2*a*, *b*), and a duration of 200–400 ms which increased during repetitive firing up to 1 s. In most cells only one or two action potentials could be elicited by maintained depolarization because of rapid adaptation; recovery could take many seconds or even minutes. Action potentials could, however, be elicited by termination of a hyperpolarizing pulse (Fig. 2*b*, *c*) even when depolarization produced no response. Addition of 5 mM $CoCl_2$ to the bathing medium reversibly suppressed action potential generation (Fig. 2*d*–*f*), indicating that Ca^{2+} is the major current carrier for the action potential.

To test for electrical coupling, pairs of cells were recorded simultaneously. We never detected responses in one cell to action potentials or applied current pulses (depolarizing or hyperpolarizing) in another (Fig. 2*c*), even when applied pulses were increased to cause eventual damage to the cell. Both neighbouring and more distant pairs of cells were tested in this way. This lack of coupling is unusual (the only other case of electrical isolation of gland cells is in the pedal gland of molluscs[9]). This property should eliminate many of the experimental problems associated with coupling in other systems[10]. For example, it is difficult to ascertain clearly whether any electrical activity observed in a given cell originates from that or from neighbouring cells, and the effective shunt resistance of the cells may vary (for example, by the actions of transmitters on cell membrane or junctional membrane permeability).

The electrical isolation of the *H. ghilianii* salivary cells is a fundamental advantage for secretion studies at the cellular level. It should be possible, for example, to study release of identified secretions from each of the five cell types, as has been done with neurotransmitters in identified invertebrate neurones[11].

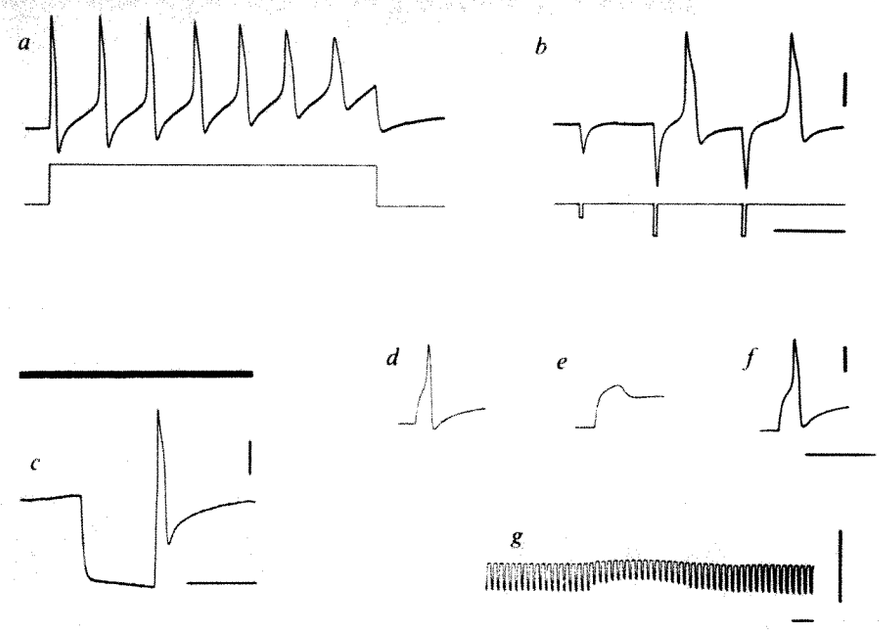

Fig. 2 Intracellular recordings from salivary gland cells of *H. ghilianii*. *a*, *b*, Action potentials, which may exceed 90 mV, are initiated by depolarizing current (*a*) and also following hyperpolarization by inward current (*b*; 100-ms pulses were applied). *c*, A hyperpolarizing current pulse in one salivary cell (lower trace) produces rebound excitation but there is no sign of electrical responses in an adjacent cell, recorded simultaneously at high gain on the upper trace. Experiments of this type indicate that the gland cells are not electrically coupled. *d*–*f*, Effect of 5 mM Co^{2+} added to the bathing solution. *d*, Control impulse in response to depolarizing current; *e*, 5 min after addition of $CoCl_2$ the action potential is abolished (a delayed rectification is apparent); *f*, recovery. This indicates that Ca^{2+} is the major current carrier for generation of action potentials. *g*, Brief application of 10^{-5} M serotonin produces a depolarization and increase in membrane conductance (indicated by reduction in amplitude of constant-current hyperpolarizing pulses). Voltage scales (vertical bars), 25 mV (1 mV in *c*, upper trace); time scales (horizontal bars), 2 s.

The natural stimulus for action potential generation, whether neural and/or hormonal, is unknown. Several putative neurotransmitters, however, (dopamine, serotonin and acetylcholine) were found to depolarize the gland cells, with an accompanying decrease in membrane resistance (Fig. 2*g*) and occasionally the production of no more than four impulses. Interestingly, in the presence of dopamine, applied depolarizing current was sometimes found to produce repetitive firing which was not simply a consequence of the depolarization produced by the drug. If the impulse provides a trigger for secretion, it seems unusual that the cells are normally so difficult to activate. Feeding, however, occurs very infrequently (every few months) and an action such as that of dopamine may mimic a natural process of bringing the gland into secreting condition.

In mammals, salivary and other exocrine gland cells are electrically inexcitable, producing graded potential changes (often hyperpolarizations) which may or may not be related to secretory function[10]. The *H. ghilianii* salivary cells are similar in their electrical excitability to mammalian endocrine cells such as those in the pancreas[12], adenohypophysis[13] and adrenal gland[14] (some molluscan exocrine glands produce action potentials[15]). This similarity extends to the anode-break excitation[8] shown by chromaffin[14] and anterior pituitary cells[13].

We have also found the *H. ghilianii* salivary gland to be suitable for molecular genetics because the cells have a very large ramifying nucleus that displays gene amplification of $\sim 10^6$ times; this should allow precise questions to be asked about the relationship between secretion and transcription/translation of identified genes. Thus, the *H. ghilianii* salivary gland, with its unusual combination of properties, represents a simple, accessible preparation with distinct experimental advantages for cellular studies of glandular secretion.

This specialized leech has been generally unavailable because in its natural habitat it is restricted to Amazonia. We have developed techniques for breeding this species and a facility has been set up by Biopharm to supply hementin to interested researchers.

Production of transgenic rabbits, sheep and pigs by microinjection

Direct microinjection has been used to introduce foreign DNA into a number of terminally differentiated cell types as well as embryos of several species including sea urchin[1], *Candida elegans*[2], *Xenopus*[3], *Drosophila*[4,5] and mice[6–11]. Various genes have been successfully introduced into mice including constructs consisting of the mouse metallothionein-I (MT) promoter/regulator region fused to either the rat or human growth hormone (hGH) structural genes. Transgenic mice harbouring such genes commonly exhibit high, metal-inducible levels of the fusion messenger RNA in several organs, substantial quantities of the foreign growth hormone in serum and enhanced growth[12,13]. In addition, the gene is stably incorporated into the germ line, making the phenotype heritable. Because of the scientific importance and potential economic value of transgenic livestock containing foreign genes, we initiated studies on large animals by microinjecting the fusion gene, *MT–hGH*[13], into the pronuclei or nuclei of eggs from superovulated rabbits, sheep and pigs. We report here integration of the gene in all three species and expression of the gene in transgenic rabbits and pigs.

Studies with mouse ova indicated that integration of a gene into host chromosomes is much more efficient with nuclear than with cytoplasmic injection[14]. On this basis, we reasoned that nuclear injection would be an appropriate first approach with other species. The first problem encountered was visualization

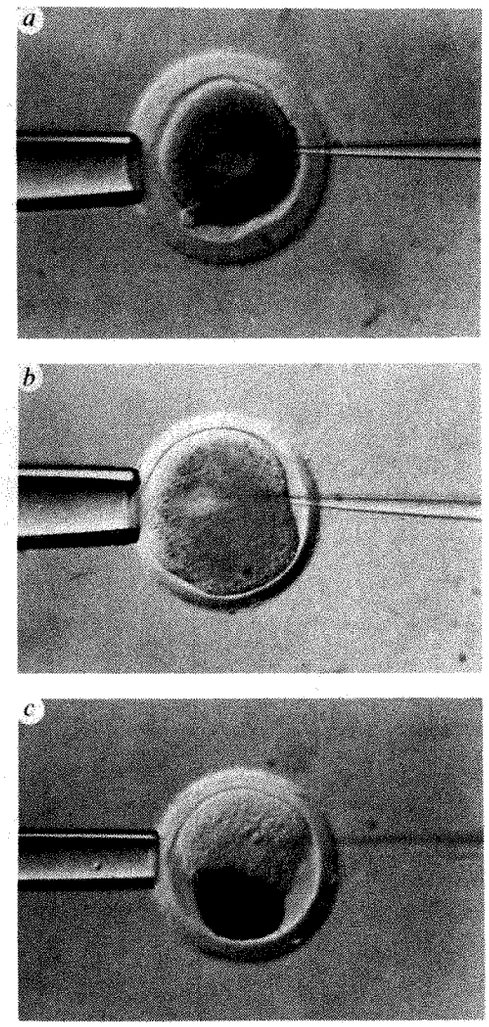

Fig. 1 Interference-contrast photomicrographs of one-cell fertilized ova from rabbit (*a*), sheep (*b*) and pig (*c*) following microinjection. Ova are held by a blunt holding pipette (diameter ~50 μm); an injecting pipette (diameter ~1.5 μm) has penetrated the zona pellucida, plasma membrane and pronuclear envelope. The tip is seen within the nucleoplasm immediately following injection of buffer containing DNA. The porcine ova (*c*) has been centrifuged at 15,000*g* for 3 min to reveal the normally obscure pronuclei[15]. Visualization of nuclear structures is aided by the use of interference-contrast optics, and microinjection is carried out under × 250 magnification using a Leitz microinjecting apparatus[10,14]. Injection was monitored by observing the diameter of the pronuclus or nucleus, which was expanded ~50%.

of the pronuclei or nuclei in the ova. Rabbit nuclear structures are readily seen (Fig. 1*a*). However, pronuclei and nuclei in sheep ova are difficult to locate and can only be seen by fluorescent microscopy using DNA specific fluorochromes (Hoechst, 33258) or by interference contrast (IC) microscopy (Fig. 1*b*). The combination of stain and ultraviolet light is damaging to the ovum (data not shown), so we used IC microscopy for microinjection. Fluorescent analysis indicated that IC microscopy is an effective method for pronuclear localization in approximately 80% of fertilized sheep eggs. Pig ova are opaque and no nuclear structures can be seen even with IC microscopy, but we found that centrifugation of pig ova at 15,000*g* for 3 min stratifies the cytoplasm (Fig. 1*c*), leaving the pronuclei or nuclei visible[15].

Once the nuclei could be visualized, microinjection was performed as described previously[10,14]. A few hundred copies of a 2.6 kilobase (kb) linear fragment containing the *MT-hGH* gene (see Fig. 2) were injected. Approximately 5,000 ova were injected and subsequently transferred to foster animals; about 500 of these resulted in fetuses or neonates (Table 1). The frequency of *MT-GH* integration was similar in the rabbit (12.8%) and the pig (11.0%) and low in sheep (1.3%). These integration efficiencies are probably accurate for the techniques being used because they are based on a large number of animals. The reasons for the lower integration frequency in these species compared to the mouse where it is ~27% are unknown but could be related to factors such as the concentration of DNA, buffer composition, age of the ovum and the structure of the chromosomes[14].

The number of copies of the *MT-hGH* gene that integrated was estimated by quantitative dot hybridization. Figure 2*d* shows the quantitation method as applied to transgenic pigs. Gene copy numbers ranged from 1 to 490 copies per cell (Table 2). The DNA from some of the transgenic animals was also analysed by restriction enzyme digestion of the chromosomal DNA followed by agarose gel electrophoresis and Southern blotting. Figure 2*a* shows the results obtained when the DNA was restricted with *Eco*RI, an enzyme that cuts once within the injected DNA. The probe detects two prominent bands in several rabbits and pigs. One band is close to the length of the injected DNA fragment (2.6 kb) and probably represents a tandem, head-to-tail array of the *MT-hGH* genes as is typically observed in transgenic mice[10,12]. The other band is approximately twice that length and might represent a head-to-head dimer, but further analysis will be required to test that possibility. When the DNA was restricted with *Sst*I (Fig. 2*b*), an enzyme that cuts twice within the injected DNA, two bands of the expected size were observed in all of the pigs and rabbits. Analysis of the sheep sample with *Eco*RI (not shown) and *Sst*I (Fig. 2*c*) revealed bands that were inconsistent with an intact *MT-hGH* gene, suggesting that the DNA had been trimmed or rearranged prior to integration.

Expression of the integrated genes was examined by quantitating *MT-hGH* mRNA by solution hybridization (Table 2). Only 4 of 16 rabbits analysed had any detectable *MT-hGH* mRNA in the liver, but the level was substantial in one of these. In mice, the frequency of expression of this gene is close to 70% (ref. 13). In pigs, mRNA levels were measured only in tail or ear samples because we did not want to risk adverse consequences of liver biopsy. Although tail and ear tissues are not primary sites of *MT* gene expression, we detected low levels of *MT-hGH* mRNA in several of the transgenic pigs (Table 2).

Plasma samples taken from pigs at birth and ~1 month later were analysed for hGH by radioimmunoassay. At birth, 11 of 18 pigs had detectable levels of hGH, ranging between 2 and 730 ng ml^{-1} (Table 2). One month later, hGH exceeded 300 ng ml^{-1} in three pigs. One rabbit also had a high level of hGH. Serum hGH as high as 64,000 ng ml^{-1} has been detected in transgenic mice, but accelerated growth rate was observed at levels of 20 to 80 ng ml^{-1} (ref. 13). None of these animals were exposed to high levels of zinc, a treatment that has been shown to activate *MT-hGH* gene expression ~10-fold in mice[13].

The effects of hGH on the growth of rabbits cannot be evaluated at present because only one live rabbit had detectable serum hGH and unfortunately it had malocclusion that impaired normal food consumption. Early indications are that the levels of hGH found in these transgenic pigs do not increase body weight dramatically. This may not be surprising considering that daily injections of bacterially synthesized hGH had no effect[16], and exogenous, highly purified porcine GH only stimulated growth by 10% when delivered during the major growth phase of the pig[17]. Transgenic offspring and littermate controls will need to be raised on normal and zinc-supplemented diets to determine precisely the effects of hGH on growth rate and other nutritional as well as endocrine parameters.

These experiments demonstrate that foreign genes can be introduced into several large animal species by microinjection of ova. Furthermore, expression of MT-hGH was obtained in rabbits and pigs. We used a fusion gene that has worked well in mice to demonstrate the feasibility of such techniques, and we are now trying several modifications in an effort to improve the level of expression and physiological response.

Table 1 Efficiency of producing *MT-hGH* transgenic rabbits, sheep and pigs by microinjection

Species	Transferred injected ova	Recipients	Integration frequency (%)	Expression frequency *MT-hGH* mRNA	Expression frequency Serum or plasma hGH
Rabbit*	1,907	73	28/218 (12.8)	4/16	1/1
Sheep†	1,032	192	1/73 (1.3)	ND	ND
Pig‡	2,035	64	20/192 (10.4)	11/20	11/18

Integration frequency is the number of animals (fetuses, stillborns and neonates) that retained the injected DNA/total number of animals resulting from injected ova. Six gilts bearing only injected eggs farrowed, producing 52 neonates, 5 of which retained DNA. In 31 gilts that farrowed, 204 fertilized control ova were transferred along with 859 injected ova to ensure sufficient embryos at implantation to maintain pregnancy. If survival of injected eggs to fetuses (16.4%) was similar for both groups, then injected eggs resulted in 140 of 252 fetuses and piglets produced, 15 of which retained injected DNA. We combined the data from the two groups to estimate integration efficiency. Expression frequency is the number of fetuses or neonates containing *MT-hGH* mRNA or plasma hGH per total number of animals examined. ND, not determined.

* Fertilized one-cell rabbit ova were flushed from the oviducts of superovulated New Zealand White (NZW) females 19 h after mating[20]. For microinjection the ova were placed in the well of a depression slide containing ~100 μl modified BMOC culture medium[21] with the $NaHCO_3$ replaced by 25 mM HEPES[22] and covered by silicone oil. Microinjection of embryos (1,857 one-cell and 50 two-cell) was performed as described for mouse ova[10,14]. Following injection, the ova were washed in fresh modified BMOC and surgically transferred to the oviducts of synchronized pseudopregnant rabbits[23].

† Rambouillet ewes were superovulated after exhibiting at least one prior oestrus period. On about day 10 of the oestrous cycle, progestagen-impregnated vaginal sponges (6α-methyl-17α-acetoxy progesterone, 60 mg; from Dr J. Lauderdale, Upjohn) were inserted and left for 12 days. Gonadotropin treatment (porcine follicle stimulating hormone, Burns) began three days before sponge removal and was continued twice daily (2.5 mg per injection, intramuscular) until the day following sponge removal[24]. At the onset of oestrus, ewes were either hand mated to fertile rams or inseminated *in utero* with 0.2 ml per horn of washed ram semen; 72 h after sponge removal, one-cell fertilized ova and cleaved ova were surgically collected from the reproductive tracts of anaesthetized ewes by flushing 6 ml Ham's F-10 medium containing 10% heat-inactivated fetal calf serum (FCS) from the utero-tubal junction through the cannulated infundibular end of each oviduct. The flushings were collected in sterile Petri dishes, and ova were removed under a dissecting scope. Ova were transferred to fresh Ham's F-10 containing 10% FCS and transported (~2.5 h) to Philadelphia in temperature-controlled containers. Microinjection of embryos (641 one-cell, 375 two-cell and 16 four-cell) was performed as previously described[10,14]. After embryos were injected, they were washed and transported to Beltsville. Embryos were aspirated into a glass micropipet tip with 10 μl Ham's F-10 and expelled 1-3 cm into the fimbriated end of the oviduct in synchronized recipient ewes. To assess the effects of transport and microinjection of DNA on egg development, a number of recipients bearing control and injected eggs were flushed 8 days following transfer. In recipients in which eggs were recovered, 26% of transported, uninjected and 10% of injected sheep eggs developed to blastocysts. Because of the high mortality of transported, injected eggs and the concern of multiple births, 5 or 6 embryos were transferred per recipient.

‡ Mature gilts were superovulated and bred as previously described[15]. At 18 to 27 h after the expected time of ovulation, gilts were anaesthetized and one cell fertilized the oviduct with 20 ml modified BMOC[21]. Ova were transferred to fresh BMOC and transported to Philadelphia. Microinjection of embryos (316 one-cell, and 1,719 two-cell) was performed as previously described[10,14]. The obscured pronuclei or nuclei or one- and two-cell pig ova were visible after centrifugation for 3 min at 15,000 g. Centrifugation of pig ova at this force and length of time has no detectable effect on development[15]. After embryos were injected, they were transported to Beltsville and transferred to the oviducts of recipient gilts as previously described[15]. To assess the effects of transport and microinjection of DNA on egg development, recipients bearing control and injected eggs were flushed 5 days following transfer. Approximately 52% of transported, uninjected and 23% of injected pig eggs developed to blastocysts. The pregnancy rate in recipients bearing only injected eggs was 50% while in recipients bearing both injected and control eggs 58% farrowed.

A 2.6-kb linear fragment of the fusion gene *MT-hGH*[13] containing the mouse MT-I regulator/promoter fused to hGH[19] was injected into fertilized one-cell and two-cell rabbit, sheep and pig eggs as described for mouse ova[10,14]. The male or female pronuclei of one-cell ova and both nuclei of two-cell ova were microinjected with a 3 ng μl^{-1} solution of DNA in Tris-EDTA buffer[14]. The ova were transferred into the oviducts of recipients at the same stage post oestrus as the donors (see Table 1). Animals without identified gender were either killed as fetuses(*) or were stillborn(†). The number of foreign fusion genes per cell was estimated by extracting total nucleic acids from a piece of fetal liver, neonatal ear or tail samples and performing quantitative dot hybridization with a 1.0-kb *Pvu*II probe spanning most of the *hGH* structural gene[19] (see Fig. 2). *MT-hGH* mRNA was measured by solution hybridization with a ^{32}P-labelled oligonucleotide (21-mer)[25]. For rabbits, either a partial hepatectomy was performed or fetal liver was used. For pigs, the *MT-hGH* mRNA content of ear or tail samples was quantitated. The concentration of *hGH* was measured in pig plasma obtained shortly after birth and serum from a 9-month-old rabbit. Samples were assayed in duplicate at 2.5 and 10 μl by radioimmunoassay using a hGH kit provided by Dr Raiti (National Hormone and Pituitary Program). The assay did not cross-react with porcine GH but required extra normal rabbit serum and anti-rabbit gammaglobulin to quantify hGH in rabbit samples. Pigs with hGH values less than 2 ng ml^{-1} at birth were designated negative for hGH. At about one month of age, these pigs were also negative for hGH. ND, not determined; Neg, negative for hGH.

The key element in our success was the ability to visualize pronuclei and nuclei. Microinjection of the *MT-hGH* gene into the cytoplasm of 485 pig ova failed to produce DNA integration in 42 fetuses. Separate techniques for sheep and pigs were necessary because the opacity of the eggs differed. Although both contain dense cytoplasm, centrifugation did not help visualize pronuclei of sheep eggs and IC microscopy did not allow nuclear localization in pig ova. Preliminary work indicates

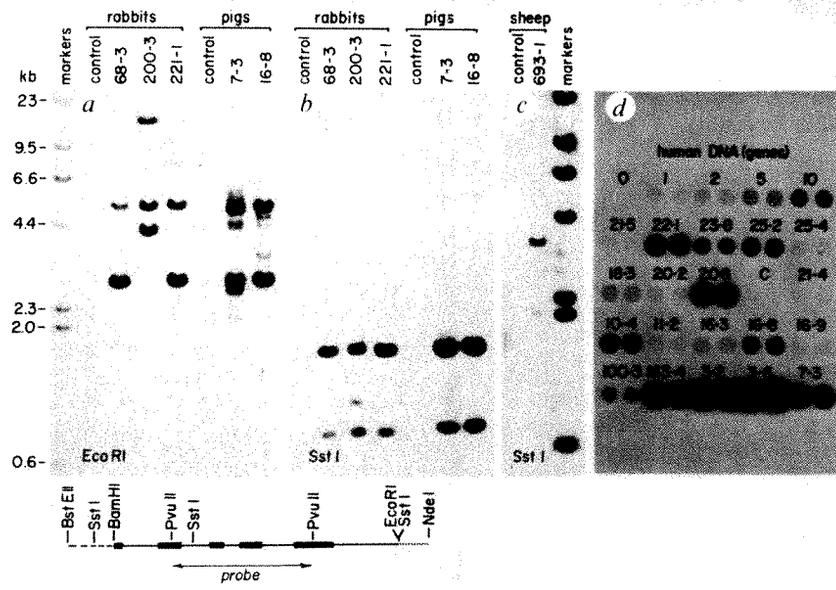

Fig. 2 Analysis of *MT-hGH* DNA introduced into rabbits, pigs and sheep. The diagram at the bottom shows the 2.6-kb *Bst*EII/*Eco*RI DNA fragment isolated from *MT-hGH* gene plasmid 111 that was microinjected[13]; the mouse MT-I promoter region is dashed, the *hGH* gene is solid, with the exons indicated as boxes, and the residual pBR322 sequences are dotted. The internal *Pvu*II fragment was isolated, nick-translated and used as a probe for quantitation of genes and Southern blots. Panels *a*, *b* and *c*: DNA (5 μg for controls and transgenic animals 200-3, 16-8 and 693-1; 1 μg mixed with 4 μg of control DNA for 68-3, 221-1 and 7-3) were digested with the indicated restriction enzymes (10 units, 6 h), electrophoresed on a 1% agarose gel, transferred to nitrocellulose and hybridized with the nick-translated probe, washed and autoradiographed as described previously[18]. *a* and *b*, Exposure was 4.5 h; *c*, 24 h. For quantitation of gene copy number, 5 μg of DNA was spotted in duplicate onto nitrocellulose along with standards of 0, 0.5, 1, 2 and 5 μg of human DNA mixed with control DNA to make a total of 5 μg. *d* Shows the visualization *MT-hGH* gene copy number in transgenic pigs. After exposure, the spots were cut out and the radioactivity determined in a scintillation counter. Gene copy numbers were calculated from the standards assuming that the genome size of pigs and humans are comparable and that diploid human cells contain 10 genes homologous to the *Pvu*II fragment used as probe[19]. The results are shown in Table 2.

that these two techniques can be used for ova of other species; for example, IC microscopy allowed visualization of pronuclei in goat ova (unpublished observations) and centrifugation allowed localization of pronuclei in cow ova[15]. Although improvements in integration efficiency should be possible, the techniques have immediate application for both scientific and practical purposes.

We thank Mary Chandlee, Dennis McDuffie, Anne Powell, Leah Schulman, Myrna Trumbauer and Mary Yagle for technical assistance and Kenneth Bender, Paul Graninger, James Piatt, David Sherman and Stephanie Mengel for animal care. This work was supported in part by grants from the USDA (Section 1433 formula funds) and NIH (HD-19018) to R.L.B. and NIH (HD-09172) to R.D.P. R.E.H. was supported by an NIH training grant (HD-07155) and K.M.E. by an NIH postdoctoral fellowship (HD-06210).

Expression of active human clotting factor IX from recombinant DNA clones in mammalian cells

D. S. Anson*, D. E. G. Austen† & G. G. Brownlee*

* Sir William Dunn School of Pathology, University of Oxford, South Parks Road, Oxford OX1 3RE, UK
† Haemophilia Centre, Churchill Hospital, Oxford OX3 7LJ, UK

Haemophilia B, or Christmas disease, is an inherited X-chromosome-linked bleeding disorder caused by a defect in clotting factor IX and occurs in about 1 in 30,000 males in the United Kingdom[1]. Injection of factor IX concentrate obtained from blood donors allows most patients to be successfully managed. However, because of impurities in the factor IX concentrate presently in use, this treatment involves some risk of infection by blood-borne viruses such as non-A, non-B hepatitis and the virus causing acquired immune deficiency syndrome (AIDS)[2]. Because of the recent concern about the increasing incidence of AIDS amongst haemophiliacs, a factor IX preparation derived from a source other than blood is desirable. Here, we report that after introduction of human factor IX DNA clones[3] into a rat hepatoma cell line using recombinant DNA methods, we were able to isolate small amounts of biologically active human factor IX.

Factor IX is a plasma glycoprotein which has an essential role in the middle phase of the intrinsic clotting pathway[4] where, in an activated form, IXa, it interacts with factor VIII, phospholipid and calcium ions to form a complex that converts factor X to Xa. Factor IX is synthesized in liver hepatocytes where it undergoes three distinct types of post-translational modification before secretion into the bloodstream as a 415-amino-acid-long, highly modified protein. These modifications are the vitamin K-dependent γ-carboxylation of 12 glutamic acid residues[5], the addition of several carbohydrate residues[6] and the β-hydroxylation of a single aspartic acid residue[7]. The first two modifications are known to be required for activity of factor IX[5,6]. Because of the complex and specialized nature of these modifications, it seemed probable that the expression of active factor IX, derived from factor IX DNA clones, would be most likely to succeed in a hepatic cell or a transformed cell line derived from a hepatocyte. None of the standard mammalian hepatoma cell

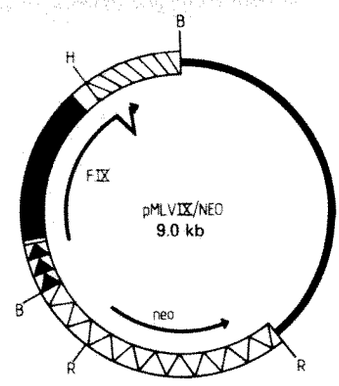

Fig. 1 Map of the expression plasmid pMLVIX/NEO. Restriction sites for *Eco*RI, *Bam*HI and *Hin*dIII are denoted R, B and H, respectively. The factor IX (abbreviated FIX) and *tk/neo* (abbreviated neo) sections are indicated by arrows which show the 5′→3′ direction of the mRNA transcribed from these genes. pAT153 sequences are indicated by the narrow solid line, the *tk/neo* gene by the zig-zag line. The factor IX transcription unit, from 5′ to 3′, consists of the M-MuLV LTR (▲), factor IX 5′-noncoding sequence (open wide line), factor IX coding sequence (solid wide line), factor IX 3′-noncoding sequence (open wide line) and SV40 sequences (diagonals).

Methods. Construction of the plasmid: The region from nucleotides 25 to 93 was removed from the factor IX cDNA cVI by digesting cVI[3] (held in the plasmid vector pAT153/PvuII/8) with *Bam*HI, followed by 'filling-in' the overhanging ends with deoxynucleoside triphosphates using the Klenow fragment of DNA polymerase I (*Escherichia coli*). After dephosphorylation with calf intestinal phosphatase, a partial digest with *Eco*RV was performed. *Eco*RV recognizes the sequence GATATC at nucleotides 91–96. A partial digest was necessary because of the presence of an additional *Eco*RV site at nucleotide 508. The resulting linear fragment of ~4.9 kb was purified by agarose gel electrophoresis. A short (0.1-kb) *Taq*I/*Eco*RV fragment was generated from the factor IX genomic DNA XI[3] by digesting XI (also held in the plasmid vector pAT153/PvuII/8) with *Taq*I, filling-in the overhanging ends with deoxynucleoside triphosphates as before in the presence of tracer amounts of [α^{32}P]dGTP and re-cutting with *Eco*RV. This labelled fragment, corresponding to nucleotides 288–386 of the genomic DNA (see Fig. 4 of ref. 3), was separated from other *Taq*I and *Eco*RV fragments derived from the plasmid vector by 6% acrylamide gel electrophoresis. The 4.9-kb and 0.1-kb fragments were ligated together and cloned in *E. coli* MC1061. One clone, designated p5′G3′cVI, contained the reconstructed factor IX gene corresponding to nucleotides 1–1,572 of the mRNA[3], effectively adding nucleotides 1–25 to, and correcting the rearrangement in, the first 15 residues of clone cVI. The clone also contained eight extra nucleotides, genomic DNA residues 288–295, derived from the presumed factor IX promoter region. The factor IX DNA insert present in p5′G/3′VI was removed by restriction with *Bam*HI and *Hin*dIII and isolated by agarose gel electrophoresis. Construction of the expression vector pMLV/NEO: pTKMoLTR1 (given by Dr J. C. Lang[20]) containing the M-MuLV LTR and the herpes simplex virus *tk* gene, was restricted with *Hin*dIII and *Bam*HI to remove the *tk* coding sequence. The remainder of the molecule (pAT153 and M-MuLV LTR) was purified by agarose gel electrophoresis, then used as a vector for cloning of an agarose gel-purified 0.9-kb *Bam* HI/*Hin*dIII fragment containing the SV40 small-t intron and early gene polyadenylation signal which was derived from pSV1[17] (given by Dr Colman). Recombinants containing the 0.9-kb fragment were identified by restriction mapping and one was chosen and designated pMLV. pMLV was restricted with *Pvu*I and *Eco*RI, and the *Eco*RI ends blunt-ended by filling in using the Klenow fragment of DNA polymerase I. The 4.4-kb *Pvu*I/*Eco*RI fragment containing the M-MuLV LTR, SV40 sequences and most of the pAT153 sequences, was purified by agarose gel electrophoresis. The *tk/neo* gene and part of the ampicillin resistance gene (*amp*^{r})[9] was purified as a *Pvu*I/*Bam*HI fragment from the cosmid vector pTM[18]. The *Bam*HI end was blunt-ended by filling in (see above). This fragment was then ligated to the pMLV-derived *Pvu*I/*Eco*RI fragment using T4 DNA ligase and recombinants selected on ampicillin. Note that the *Pvu*I site interrupts the *amp*^{r} gene so that in this ligation the *amp*^{r} gene was reconstructed in part from one fragment and in part from the other. The structure of recombinants was checked by restriction mapping and one clone, designated pMLV/NEO, was used in the next stage. The isolated factor IX DNA from stage 1 (above) was ligated into the *Hin*dIII site of the expression vector pMLV/NEO using T4 DNA ligase and the Klenow fragment of DNA polymerase I. Clones containing the factor IX DNA insert in the correct orientation were identified by restriction mapping, and one such clone, pMLVIX/NEO, was used for transfection.

lines secretes active endogenous factor IX. The rat hepatoma line H4-11-E-C3, however, is known to secrete a biologically active form of another vitamin K-dependent clotting factor, prothrombin[8], indicating the presence of an active γ-carboxylase system; therefore we chose this cell line for our studies.

We first constructed a factor IX expression plasmid (Fig. 1) from previously isolated human complementary DNA and genomic clones as follows. A full-length factor IX cDNA clone, p5′G/3′cVI, was assembled from the cDNA clone cVI[3] and a small fragment of genomic factor IX sequence encoding the 5′-noncoding sequence of the normal mRNA and the first domain of the protein. The resulting cDNA sequence was then placed under the transcriptional control of the promoter of the long terminal repeat (LTR) of Moloney murine leukaemia virus (M-MuLV). The transcription unit was completed by placing the simian virus 40 (SV40) small-t-antigen intron and early polyadenylation signal downstream of the factor IX coding sequence. The plasmid also contains the *tk/neo* gene[9] in order to provide a dominant selectable marker for expression in mammalian cells. In preliminary experiments, we tested the expression plasmid pMLVIX/NEO, by transfecting[10] mouse fibroblast Ltk$^-$ cells and selecting permanent cell lines for resistance to the antibiotic G418 (ref. 11). One cell line was characterized in detail and secreted detectable human factor IX in an enzyme-linked immunosorbent assay, but the secreted factor IX failed to adsorb to barium sulphate (see Fig. 2 legend and ref. 12 for assay details). Thus, the expression plasmid was proved functional in producing a protein. However, as expected, the mouse fibroblast cell line lacked the enzymes required for γ-carboxylation of the N-terminal glutamyl residues of factor IX, which are necessary for its biological activity.

The rat hepatoma line H4-11-E-C3 (see above) was transfected with the factor IX expression plasmid by standard calcium phosphate precipitation methodology[10]. Cells containing a functional *tk/neo* gene were selected for G418 resistance[11] and 24 of the resultant colonies were cloned by limiting dilution. These permanent cell lines were then grown up and the growth medium of each assayed for the presence of secreted human factor IX by ELISA (see Fig. 2 legend). Four of the cell lines secreted detectable levels of factor IX and the highest producer, line 4A, was chosen for further analysis. Southern blot analysis indicated that there was only one copy of the plasmid integrated into the chromosomal DNA per cell (data not shown). Northern blot analysis of total cellular RNA derived from line 4A revealed the presence of a factor IX mRNA species of ~1.6 kilobase (kb), which is the expected size of factor IX mRNA. On both Southern and Northern blot analysis, no cross-hybridizing species were detected in the control hepatic cell line H4-11-E-C3 (data not shown).

Figure 2 shows the time course of secretion of human factor IX by line 4A as measured by a specific, quantitative ELISA (see Fig. 2 legend); from this experiment, we estimate the rate of secretion of factor IX to be ~6 ng per 10^7 cells per 24 h. Furthermore (see Fig. 2), adsorption of the secreted factor IX onto barium sulphate[12], a procedure which depends on the γ-carboxylation of factor IX, suggests that the protein is γ-carboxylated. As the recovery of factor IX was not corrected for any losses during the experimental procedure, we cannot distinguish between the possibility that either about 70% of the material has γ-carboxyglutamic acid residues or, alternatively, that the material is all γ-carboxylated and there were losses of ~30% during recovery of the protein. No factor IX was detectable in lysates of the 4A cells, indicating that there was insignificant accumulation within the cell. No cross-reacting material was detected either in control H4-11-E-C3 conditioned media or in cell lysates.

Table 1 shows the results of a clotting and antigenic analysis of a sample of affinity-purified human factor IX from conditioned medium of line 4A cells, together with an analysis of a parallel control sample of H4-11-E-C3 cells. The purified human

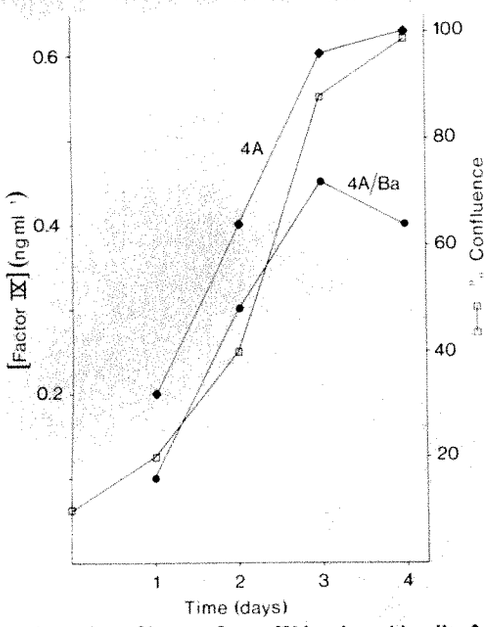

Fig. 2 Secretion of human factor IX by clone 4A cells. ◆, Factor IX levels; ●, factor IX recoverable by barium sulphate adsorption; □, degree of confluency.

Methods. Cells were seeded at 10% confluency in an 80-cm^2 flask containing 10 ml of minimal essential medium (MEM: 10% fetal calf serum containing penicillin, streptomycin, kanamycin and 100 ng ml^{-1} vitamin K). The medium was changed every 24 h and the conditioned medium assayed for human factor IX by ELISA. The ELISA was done by first binding 0.2 ml of a mouse anti-factor IX monoclonal antibody 3A6[14], diluted 1: 5,000 in 200 mM sodium carbonate *p*H 9.0, to microtitre wells at room temperature for 2 h. Samples (150 μl) of conditioned medium were then bound overnight at 4 °C. The second antibody, 150 μl of rabbit anti-human factor IX (Calbiochem-Behring), diluted 1:500 in PBS, 1% NP40 and 10% horse serum, was then bound at room temperature for 2 h. The third antibody, peroxidase-conjugated swine anti-rabbit IgG (Dako), was bound in the same manner. The assay was finally developed with 0.2 ml of 40 mM ABTS (azinodi-(3-ethylbenzthiazole sulphonic acid)-diammonium salt) in 0.008% H_2O_2 in 50 mM citrate buffer *p*H 4.0 for 30–45 min. Colour change of the solution was measured at 405 nm in a spectrophotometer. A standard curve was constructed using twofold dilutions of normal plasma in the range 10^{-3}–10^{-5} dilution, assuming a concentration of 5 μg ml^{-1} (ref. 1) for plasma factor IX. Undetectable quantities (<0.02 ng ml^{-1}) of factor IX were observed in conditioned medium from control H4-11-E-C3 cells using ELISA.

factor IX is active in a one-stage clotting assay[13], giving 7% of the activity of normal plasma. The control shows only 1% activity and this is presumably due to the trace amounts of bovine factor IX which were found in both line 4A and control samples, as indicated by an ELISA for bovine factor IX antigen (see Table 1). Further evidence (Table 1) that the cell line 4A is secreting active human factor IX is provided by the inhibitory effect of the specific anti-human factor IX monoclonal antibody 3A6[14] in the clotting assay. Control experiments showed that this antibody does not significantly inhibit bovine or rat factor IX activity at the concentration used here (data not shown). The fact that the activity level (7% of normal plasma) in the line 4A sample correlates well with the level of human factor IX antigen (6.8% of normal plasma) suggests that the protein is fully active. We conclude that line 4A cells secrete biologically active human factor IX, albeit at a low level.

We are testing alternative expression plasmids and attempting to isolate improved cell lines which might secrete more factor IX, thus facilitating purification of larger amounts of material. This should allow a detailed examination of the properties of the genetically engineered factor IX protein in comparison with the plasma protein, and should eventually allow us to start *in vivo* experiments of the kind necessary for the development and testing of a therapeutic product. For example, it is important to determine the half-life and efficacy of the genetically

Table 1 Analysis of clotting factor IX activity and of human and bovine factor IX antigen in purified samples from 4A and H4-11-E-C3 conditioned media

Assay	Cell line 4A	H4-11-E-C3
Clotting (%)	7	1
Clotting (%) + 3A6 antibody	<1	<1
Human IX antigen (%)	6.8	ND
Bovine IX antigen	0.8	1.2

Factor IX clotting activity (measured using the one-stage clotting assay[13] in which factor IX-deficient plasma is used as a substrate), and human factor IX antigen (measured by ELISA) are both given as percentages of average normal plasma levels. The inhibitory effect of the monoclonal antibody 3A6 was measured by preincubation of the sample to be tested with a final concentration of 2.5% 3A6 ascites fluid for 15 min at room temperature. Bovine antigen is given in arbitrary units and was assayed by quantitative ELISA as follows. Dilutions of pure bovine factor IX or samples to be assayed were diluted in 200 mM sodium bicarbonate, *p*H 9.0 buffer and dried onto microtitre plates. Bovine factor IX was then detected using a polyclonal rabbit anti-bovine factor IX antibody and a peroxidase-conjugated anti-rabbit IgG antibody as for the ELISA for human factor IX. The human factor IX sample from 1.5 l of conditioned media from line 4A cells, and the control sample from the same volume of H4-11-E-C3 cells were purified by barium citrate adsorption[16] and immunoaffinity chromatography. An anti-human factor IX antibody affinity column was prepared by binding the 3A6 monoclonal antibody (purified from ascites fluid by sodium sulphate precipitation) to the support Affigel 10 (Biorad) using conditions recommended by the manufacturer. The sample to be bound was passed twice over the column (vol. 0.3 ml) then washed with >100 vol. phosphate-buffered saline (PBS)), 1% Nonidet P-40 (NP40) and a similar volume of PBS, 1 M NaCl, 1% NP40. Finally, the column was rinsed with 5 vol. PBS, 1 M NaCl and eluted with 7 M urea, 1 M NaCl, and 0.4-ml fractions were collected. The first three fractions were pooled and immediately dialysed overnight against 2% PBS at 4 °C, followed by freeze-drying. The samples were finally dissolved in 200 μl H_2O. ND, not determined.

engineered product compared with plasma factor IX. A clinical product derived from the cell line described here is therefore not an immediate prospect, but the results reported here represent an important first step in demonstrating the feasiblity of this approach. However, we are optimistic that further studies in conjunction with work already done on clotting factor VIII(C)[15,19], will eventually allow the majority of haemophiliacs to be treated with improved virus-free products.

We thank Professor A. Bloom and Dr Ian Peake for the gift of anti-factor IX monoclonal antibody 3A6, Dr M. P. Esnouf for the gifts of pure bovine factor IX, rabbit anti-bovine factor IX antiserum and vitamin K, and the Schering Corporation for G418. We also thank Dr Charles Rizza, Dr Ian Jones and Peter Winship for useful discussions, and Barbara Paxman for secretarial help. This work was supported by MRC project grant G8405633CB to D.S.A. and G.G.B.

Lattice mobility and anomalous temperature factor behaviour in cytochrome *c'*

B. C. Finzel & F. R. Salemme*

Protein Engineering Division, Genex Corporation,
16020 Industrial Drive, Gaithersburg, Maryland 20877, USA

Atomic temperature factors (*B*-values) obtained from X-ray refinement experiments provide empirical estimates of protein mobility that have been correlated with both theoretical simulations of protein dynamics[1] and experimental studies of antibody reactivity[2,3]. The comparison of *B*-values with protein solution properties requires adjustment of the apparent atomic mobilities to compensate for the effects of the crystal environment[4–6]. Here we compare crystallographically independent subunits of the dimeric cytochrome *c'* from the bacterium *Rhodospirillum molischianum* to examine how lattice effects influence refined *B*-values. In addition to local effects on protein mobility at crystal contacts[4,5], we show that *B*-value differences up to 12 Å^2 between subunits result from lattice disordering effects that approximate to concerted rotations of the molecules about a crystal symmetry axis.

Ferricytochrome *c'* from *R. molischianum* is a dimeric haem protein composed of identical 128-residue polypeptide chains. The protein crystallizes in the orthorhombic space group $P2_12_12_1$ ($a = 56.6$, $b = 72.4$, $c = 75.4$ Å), with a dimer in the crystallographic asymmetrical unit[7]. The structure has been crystallographically refined to an *R*-factor of 0.19 for 30,533 reflections with $F > 2\sigma F$ to 1.67 Å resolution[8]. Independently refined subunits are related by a non-crystallographic dyad axis with an r.m.s. difference between corresponding α-carbon positions of 0.40 Å. Many detailed features of the subunits, including the equivalent situations of some 40 bound solvent molecules per monomer, are conserved despite differing environments in the crystal lattice.

Figure 1*a,b* plots mean residue *B*-value against sequence number for the two subunits of the native dimer. Comparison of the subunits yields a correlation coefficient of 0.82. This is similar to values reported for structures determined in different crystal forms[5,9] and is indicative of the extent to which *B*-value behaviour may reflect intrinsic protein dynamical properties[1,4]. Despite the similarities, monomer *B*-values differ by up to 30 Å^2 locally and by some 6 Å^2 overall (Fig. 1*c*). These variations between chemically identical subunits are attributable to their different environments in the crystal lattice.

Lattice interactions could potentially affect *B*-value behaviour in a variety of ways[6]. One result of the intermolecular interactions formed at crystal contacts is the localized immobilization of protein side chains or surface backbone loops. Consequently, the *B*-values of groups involved in such interactions may imply local mobilities that are substantially smaller than actually occur in solution. Previous studies have correlated the magnitude of such localized effects with solvent-accessible surface area in the crystal lattice[5,10]. Comparison of the mean residue *B*-values and fractional accessible surface areas[11] for the individual cytochrome *c'* subunits yields correlation coefficients (0.69 and 0.61, Fig. 1*a, b*) comparable to those observed previously[5,10]. A difference plot between monomers (Fig. 1*c*) shows that *B*-value and accessible area variations frequently correspond to alternative lattice contacts made by the two monomers in the asymmetrical unit. Nevertheless, differences between monomers correlate relatively poorly (0.35), in part resulting from an average difference of 6 Å^2 in subunit *B*-value that is uncorrelated with any overall difference in accessible surface area. As shown below, these variations reflect a second type of lattice effect that involves systematic disordering of molecules relative to crystal symmetry axes.

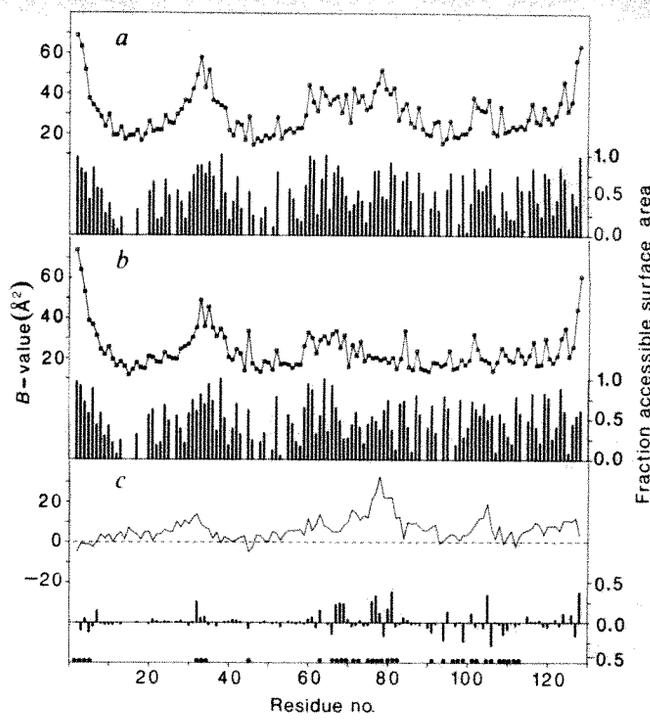

Fig. 1 *a, b*, Plots of residue *B*-value averaged over main-chain backbone atoms (connected curves), and fractional accessible surface areas[5,11] for entire residues in their respective crystal lattice environments (bars), against sequence number for crystallographically independent subunits of cytochrome *c'*. *c*, *B*-value (solid curve) and accessible surface area (bars) difference between subunits. Dots indicate sequence positions of residues that make different crystal contacts in the two subunits.

Figure 2 shows the crystal packing geometry and illustrates that subunits with sytematically low *B*-values (cool monomers) form continuous lattice interactions along alternate 2-fold screw axes parallel to the unit cell *c*-axis. Hot monomers make native dimer interactions with cool monomers aligned along each crystal screw, together with lattice contacts to cool monomers aligned along adjacent *c*-axis screws (Fig. 2*a*). Hot monomers interact only with cool monomers and are not in contact with each other in the crystal lattice. The crystal is thus organized as a parallel array of native dimer helices that are interconnected through hot monomer lattice interactions. This situation raises the possibility of systematic disordering of the hot monomers relative to the cool monomer arrays aligned along the *c*-axis crystallographic screws.

Figure 3 plots differences in mean *B*-value (ΔB) between corresponding residues of hot and cool monomers in the native dimer against their difference in radius (ΔR) from the *c*-axis crystallographic screw. This treatment compensates for variations in *B*-value that may arise from the local structural properties of the monomers (for example, extent of local secondary structure) and emphasizes differences that vary systematically relative to the crystallographic screw axis. The observed correlation (0.57) between ΔB and ΔR for dimer subunits indicates a continuous increase in average temperature factor for residues progressively more distant from the crystallographic screw. This behaviour is consistent with either static or dynamic lattice disordering phenomena involving rotational or wobbling displacements of the dimers relative to the crystal screw axis. The average behaviour (Fig. 3) suggests a maximum *B*-value contribution of 12 Å^2 at the hot monomer periphery resulting from extended lattice disordering effects. Assuming the simplest model involving rigid-body displacement of the dimer about the

* Present address: E. I. DuPont de Nemours Experimental Station, Central Research and Development Department, Wilmington, Delaware 19898, USA.

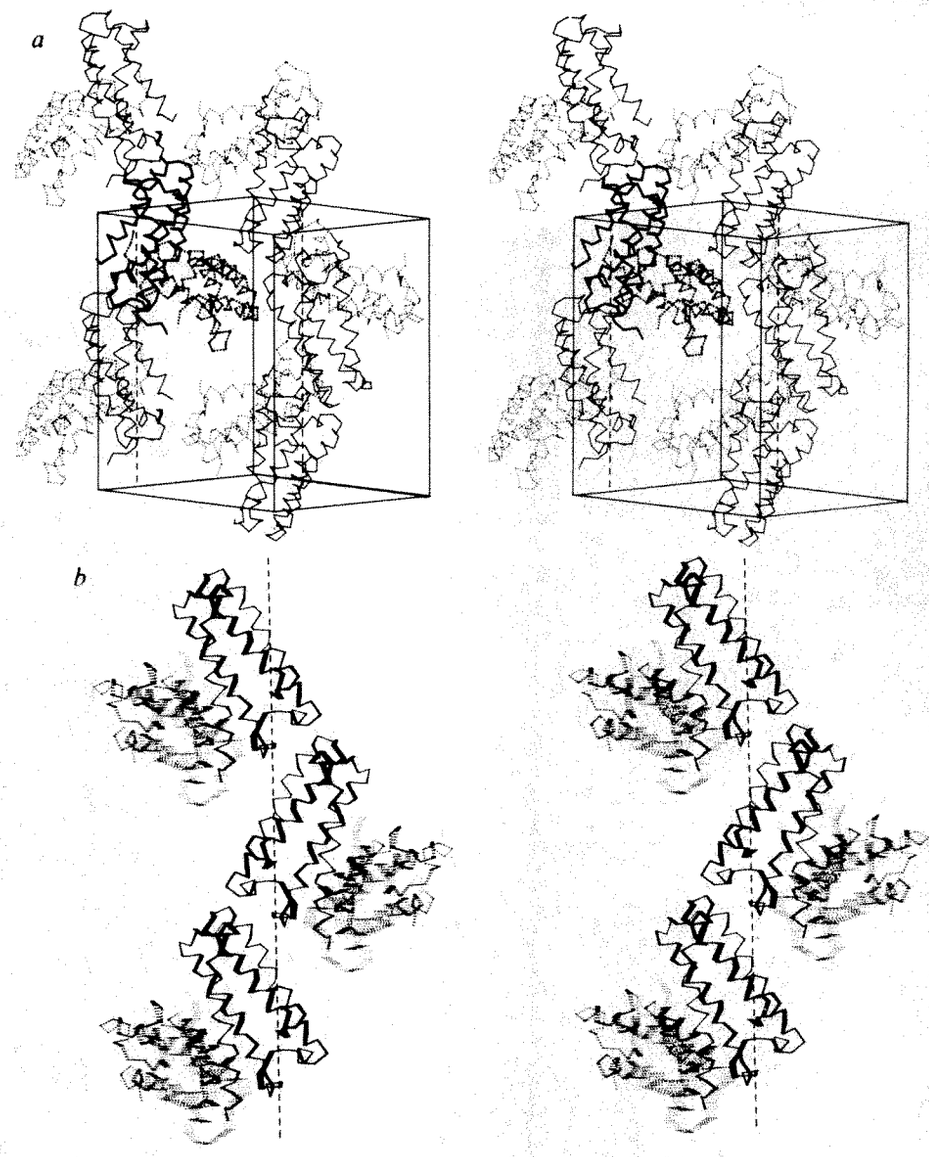

Fig. 2 *a*, Stereoview of the cytochrome *c'* crystal packing. Subunits (illustrated by α-carbon backbones) with lower average *B*-values (cool, solid) pack continuously along alternate 2-fold screws (long dashed) parallel to the unit cell (outlined) *c*-axis. Hot (dashed) monomers hold the lattice together by making native dimer (bold) interactions with each cool monomer array and lattice contacts with cool monomer arrays on adjacent screws. *b* Shows how the systematic *B*-value differences between monomers could reflect static or dynamic disordering involving rigid-body displacements of the molecular arrays about the *c*-axis screws. The observed *B*-value difference of 12 Å^2 at the hot monomer periphery (Fig. 3) suggests an axial rotation of 1.2° that produces a maximum displacement $U = 0.7$ Å, where $U^2 = 3B/8\pi^2$. The figure illustrates the superimposed effects of a rigid body rotation about the *c*-axis crystallographic screw that has been exaggerated by a factor of 3 for clarity.

crystallographic screw yields a corresponding r.m.s. amplitude of 0.7 Å (Fig. 2*b*).

The preceding experiment shows that observed differences in subunit *B*-factor behaviour in cytochrome *c'* result from a superposition of localized lattice packing effects that correlate with accessible surface area, and long-range disordering phenomena that reflect the extended pattern of molecular interactions in the crystal lattice. In the present case, the apparent motion may be related to a low-frequency vibrational mode of the V-shaped dimer, as suggested by the correlation (0.40) of monomer *B*-values with distance to the molecular dyad axis. Such concerted molecular flexing could produce the observed overall *B*-value behaviour, assuming that the cool monomers are relatively constrained in their aligned orientations along the *c*-axis crystallographic screws.

The comparison of protein structures determined in different crystal environments provides a basis for correcting *B*-values to account for the localized immobilizations that occur at crystal contacts[4,5], and thus allows estimates of protein dynamic flexibility in solution. Nevertheless, it is clear that extended lattice disordering effects, which may be unrelated to protein solution dynamics, can make comparable contributions to refined crystallographic *B*-values. It is anticipated that similar effects could occur in other high-resolution crystal structure determinations. However, such lattice effects could go unrecognized in the general case where the crystal asymmetrical unit contains only a monomer. In this case, the potentially non-uniform contributions to *B*-values from lattice disordering would be erroneously

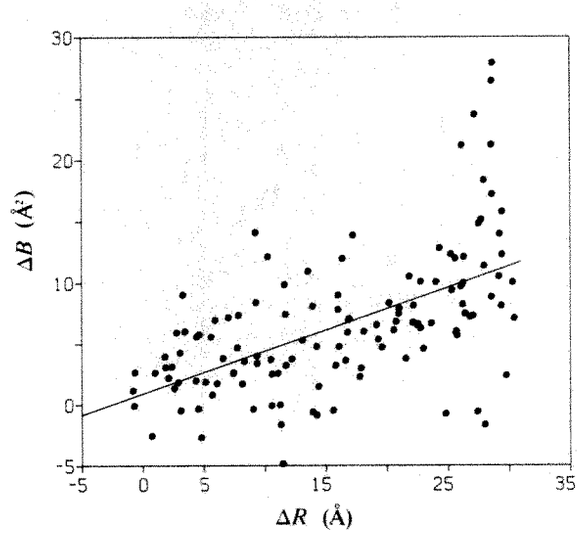

Fig. 3 Plot of the difference in mean backbone *B*-value (ΔB) between corresponding residues of the cytochrome *c'* subunits against their difference in radial distance (ΔR) from the crystal screw on which the cool monomers are aligned. The least-squares line suggests that the component varying systematically with ΔR contributes up to 12 Å^2 to the *B*-values of residues furthest from the crystal screw. Large deviations from the least-squares line correspond to residues forming different crystal contacts in the two monomer environments.

attributed to localized protein flexibility in solution. The significance attached to protein *B*-values, both in theoretical studies of protein dynamics[1] and practical applications of medical importance[2,3], justifies continued efforts at developing new theoretical and crystallographic refinement methods that can simulate crystal lattice effects.

We thank S. Sheriff for useful discussions and assistance with correlation plot software. This work was supported in part by NIHGMS grants 33325 and 30393.

Yeast heat-shock protein of M_r 48,000 is an isoprotein of enolase

Hidetoshi Iida & Ichiro Yahara

The Tokyo Metropolitan Institute of Medical Science, 3-18 Honkomagome, Bunkyo-ku, Tokyo 113, Japan

Exposure of cells or tissues of various living organisms to elevated temperatures induces the synthesis of a family of specific proteins called heat-shock proteins (HSPs)[1–3]. This phenomenon has so far been investigated mostly with respect to the induction mechanism of these HSPs[4,5]. However, little is known about the function of such proteins, although it has been suggested that they are involved in the acquisition of thermal tolerance[3]. We have recently suggested that a specific class of HSPs may function as negatively regulatory molecules in the growth of eukaryotic cells[6–8], and that a HSP of relative molecular mass (M_r) 48,000 (HSP48) from the yeast *Saccharomyces cerevisiae* may be involved in both thermal tolerance and growth control in this organism[8]. We now present evidence that *S. cerevisiae* HSP48 is an isoprotein of a glycolytic enzyme, enolase (EC 4.2.1.11). This unexpected finding may provide new insight into the role of the protein in the acquisition of thermal tolerance and growth control.

In *S. cerevisiae*, 6 out of 13 HSPs, including HSP48, are durably induced when cells are induced to enter the resting state of the cell cycle, G_0 (ref. 7). These G_0 yeast cells are much more resistant to heat shock than are growing cells, probably because of the accumulation of some or all of the above six HSPs. Induction of certain HSPs was also found with cultured cells of higher eukaryotes when they were arrested in G_0 (ref. 7). Furthermore, we have isolated a heat-shock-resistant mutant of the yeast which is defective in the *HSR1* gene and which constitutively synthesizes six proteins, including two isoforms of HSP48 (ref. 8). The *hsr1* mutant reveals unusual properties involved in growth control, in addition to the selected property that it is ~1,000-fold more resistant to lethal heat shock than the parental *HSR1* strain[8]. Because HSP48 is the only protein that is commonly induced in both growing *hsr1* cells and pre-heated or G_0-arrested *HSR1* cells, all of which are highly heat-shock resistant, we believe that HSP48 is responsible for the heat-resistance associated with these cells[8]. This is compatible with previous findings indicating that neither the products of the amplified *HSP90* genes[9] nor those of the two cloned genes of the *HSP70* family[10] are directly involved in the acquisition of resistance to lethal heat shock.

Table 1 Physicochemical and biochemical properties of HSP48 and yeast enolase

	HSP48	Enolase
Sedimentation coefficient ($s^\circ_{20,w}$)	5.3S	6.0S*
Stokes radius (Å)	36.5	36.2†
M_r from $s^\circ_{20,w}$ and Stokes radius	90,000	96,000
M_r from sedimentation equilibrium	84,000	88,000*
M_r from SDS-PAGE	48,000	48,000*
Enolase specific activity	69 ± 1	68 ± 1

Enolase activity was determined by monitoring the increasing rate of absorption at 240 nm at 25 °C as a result of conversion of D(+)2-phosphoglyceric acid (PGA) to phosphoenolpyruvate (PEP)[20]. Standard assay buffer consisted of 50 mM Tris-HCl (*p*H 7.8 at 25 °C), 2.7 mM magnesium acetate, 0.01 mM EDTA and 1.2 mM PGA. Specific activity is defined as the conversion of 1 μmol PGA to PEP per min per mg protein. Yeast enolase was a product of Oriental Yeast Co. Ltd, Tokyo.

* Data from ref. 21; † data from ref. 22.

Table 2 Amino-acid composition of HSP48 and yeast enolase

	HSP48	Yeast enolase
Asx	11.7	11.6
Thr	4.8	4.7
Ser	6.5	7.2
Glx	8.2	7.9
Pro	3.5	3.5
Gly	8.8	8.6
Ala	13.3	12.8
Val	7.4	7.9
Met	1.1	1.2
Ile	5.3	5.1
Leu	9.7	9.3
Tyr	2.1	2.1
Phe	3.7	3.7
His	2.4	2.6
Lys	8.2	8.6
Arg	3.2	3.3

Values are represented in mol%. Purified HSP48 was resolved in 7.5% SDS-PAGE[23]. The gel was not fixed or stained. Gel slices containing HSP48 were incubated in 0.02% SDS solution (1.0 ml per cm^3 gel) to elute the protein, and the elution was repeated. The combined eluates were extensively dialysed against distilled water for 2 days and lyophilized. The protein was hydrolysed in 6 M HCl at 110 °C *in vacuo* for 22 h and 70 h and analysed in an automatic amino-acid analyser (Hitachi model 835, Hitachi). Amino-acid composition of yeast enolase (peptide 1) was calculated from the amino-acid sequence of this protein deduced from the nucleotide sequence of the complementary DNA[12]. Cys and Trp residues were omitted from the above calculation as we did not determine the content of Cys or Trp in HSP48.

To elucidate the function of HSP48, extracts of yeast cells in the stationary phase underwent four successive purification steps and HSP48 was purified to homogeneity (see Fig. 1 legend). Purified HSP48 is composed of two isoforms, HSP48A (acidic form) and HSP48B (basic form)(Fig. 1*A*), as we have shown previously[7,8] by two-dimensional non-equilibrium *p*H gradient electrophoresis/SDS-polyacrylamide gel electrophoresis (NEPHGE/SDS-PAGE) of ^{35}S-methionine-labelled cells. Peptide mapping confirmed that the purified protein is identical to ^{35}S-methionine-labelled HSP48 (Fig. 1*B*).

We determined the N-terminal 23 amino acids of the purified HSP48 on a gas phase sequencer (Fig. 2). Using the Dayhoff protein sequence bank[11] to compare the sequence with those of other proteins, we found that the N-terminal 23 amino-acid sequence of HSP48 is identical to the corresponding sequence of yeast enolase (Fig. 2). In addition, physicochemical properties (Table 1) and amino-acid composition (Table 2) of the purified HSP48 were essentially the same as those of yeast enolase. Furthermore, the specific activity of the enolase in the purified HSP48 protein was the same as that of the authentic yeast

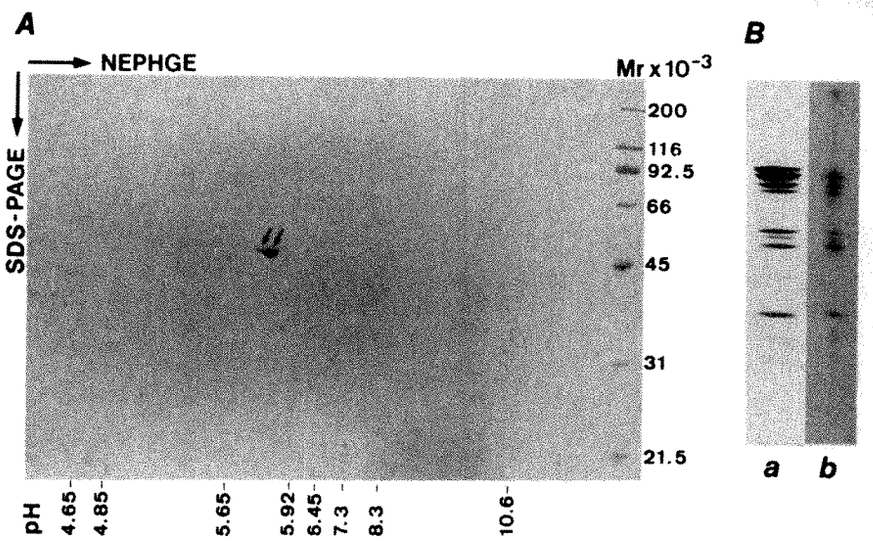

Fig. 1 *A*, Two-dimensional gel electrophoresis of purified yeast HSP48 (5 μg). *B*, peptide mapping of purified HSP48 (lane *a*) and ^{35}S-methionine-labelled HSP48B recovered from the corresponding spot in a two-dimensional gel (lane *b*).

Methods. *A*, Isolation of HSP48: Cells of strain X2180-1A (ref. 6) were grown to stationary phase at 23 °C with aeration in SD10 medium[6] in two 2.5-l batches (1×10^8 cells per ml), after which the cultures were incubated for 24 h in the same conditions. After chilling the cell suspensions, we collected the cells by centrifugation at 4 °C at 5,000 r.p.m., and washed them once with 0.05 M Tris-HCl (*p*H 7.9 at 4 °C). The pelleted cells were 35 g in wet weight, and were stored at −80 °C until use. Half of the frozen cells were thawed and suspended in 20 ml of buffer A (0.05 M Tris-HCl, *p*H 7.9 at 4 °C, 0.01 M $MgCl_2$, 0.01 M 2-mercaptoethanol, 0.1 mM EDTA, 0.25 M mannitol, 1 mM phenylmethylsulphonyl fluoride), after which they were homogenized at 4 °C with 120 g of 0.5-mm glass beads in a Universal Homogenizer (Nihon Seiki Seisakusho Co., Tokyo) for 3 × 2 min. The homogenate was centrifuged at 5,000 r.p.m. at 4 °C for 5 min, after which the resulting pellet was again homogenized and centrifuged. The supernatants were combined (58 ml) and centrifuged at 35,000 r.p.m. in a Beckman Type 35 rotor (Beckman Japan) for 2 h at 4 °C. The supernatant containing most of the HSP48 was dialysed twice against 2 l of buffer B (0.05 M Tris-HCl, *p*H 8.8 at 4 °C, 0.01 M 2-mercaptoethanol, 1 mM $MgCl_2$, 0.1 mM EDTA, 0.02 M NaCl) for 24 h at 4 °C, and applied to a DEAE-cellulose (Watman DE52) column (3 × 24 cm) equilibrated in buffer B. HSP48 was recovered in the flow-through fractions in buffer B. The fractions were combined and dialysed twice against buffer C (0.01 M sodium phosphate, *p*H 5.5 at 4 °C, 0.01 M 2-mercaptoethanol, 1 mM $MgCl_2$, 0.1 mM EDTA) for 20 h, and applied to a CM-Sepharose CL-6B column (1.4 × 20 cm) equilibrated with buffer C. HSP48 was recovered in flow-through fractions. One-tenth of the combined fractions containing HSP48 was loaded onto a Sephacryl S-200 column (1.5 × 75 cm) equilibrated with buffer D (0.01 M sodium phosphate, *p*H 6.0 at 4 °C, 0.01 M 2-mercaptoethanol, 1 mM $MgCl_2$, 0.1 mM EDTA) and eluted at a flow rate of 10 ml h^{-1}. HSP48 was eluted in a single peak and found to be purified to 99% homogeneity as judged by SDS-PAGE. The HSP48 content of fractions obtained during the purification was determined by densitometry after one-dimensional and two-dimensional SDS-PAGE. About 15–19 mg of purified HSP48 was reproducibly obtained from 17.5 g (wet weight) of yeast cells in the stationary phase with the recovery of 65%. Two-dimensional gel electrophoresis: The purified HSP48 was lyophilized, dissolved in the O'Farrell lysis buffer, and resolved by NEPHGE[24], followed by second-dimension electrophoresis in 11% SDS-PAGE[25]. The gels were stained with Coomassie brilliant blue. M_r (Bio-Rad) and isoelectric point (BDH) markers were used[8]. *B*, Cells grown in the stationary phase in synthetic medium (6.7 g l^{-1} Bacto yeast nitrogen base without amino acids, 10 g l^{-1} succinic acid, 6 g l^{-1} NaOH, 2 g l^{-1} glucose) were pulse-labelled with 10 μCi ml^{-1} L-^{35}S-methionine (1,200 Ci/mmol, Amersham Japan) at 23 °C for 10 min, and chased for 3 min by the addition of non-radioactive methionine to 0.5 mg ml^{-1}. The whole-cell extracts were resolved by two-dimensional NEPHGE/SDS-PAGE. ^{35}S-Methionine-labelled HSP48B, cut out from the corresponding spot in the gel, and purified HSP48 (5 μg) were separately subjected to peptide mapping with *Staphylococcus aureus* V8 protease (5 ng for each) according to the method of Cleveland *et al.*[26]. Lane *a*, digested products of purified HSP48 stained with Coomassie brilliant blue; lane *b*, digested products of ^{35}S-methionine-labelled HSP48B revealed by fluorography. We have previously shown that HSP48A and HSP48B give similar peptide mapping results[7,8].

enolase (Table 1). Lastly, a rabbit antiserum directed against yeast HSP48 reacted to authentic yeast enolase (Fig. 3*A*). From these results, we conclude that yeast HSP48 is enolase.

Searching for further homology between the partial amino-acid sequence of HSP48 and other proteins, we found that the 23 amino-acid N-terminal sequence of HSP48 and the N-terminal 41 amino-acid sequence of yeast enolase[12] were similar in part to the most extensive homologous region[13] found in *Drosophila* HSP70, yeast HSP70 and in the *Escherichia coli* heat-shock *dnaK* protein (Fig. 2). This partial homology suggests an evolutionary relationship between enolase and the HSP70 family. The possibility that enolase and the HSP70 family share a common function (for example, an interaction with the substrate of enolase) remains to be investigated.

An immune blot analysis of total yeast-cell proteins showed that two proteins, HSP48 and another protein of M_r 47,000 (p47), reacted with anti-HSP48 serum (Fig. 3*A*). Peptide mapping indicated that HSP48 and p47 are quite similar (Fig. 3*B*), suggesting that the latter is another isoprotein of enolase. Unlike HSP48, the synthesis rate of p47 was not significantly altered by heat shock or growth arrest (Fig. 3*C*). *S. cerevisiae* contains two non-tandemly repeated enolase structural genes, designated *ENO1* and *ENO2* (ref. 12). Enolase 2 polypeptide, the product of *ENO2*, migrates faster than enolase 1 polypeptide, the product of *ENO1*, in SDS-PAGE and the contents of the two enolase polypeptides differ with the growth conditions[14]. We found that the levels of HSP48 and p47 present in cells grown in media containing various carbon sources were quantitatively different (data not shown). Because of this and because of similarities in relative molecular mass, we conclude that HSP48 and p47 are identical to enolase 1 and enolase 2, respectively.

As is the case for HSP48 (HSP48A and HSP48B), p47 is also composed of two isoforms (Fig. 3*C*). The relative amounts of the two isoforms in each of the two proteins also differ for cells grown in different conditions[7,8], and it is possible that the enolase activities associated with these isoforms and their intracellular distribution also differ. Thus, the differential expression of the two enolase genes and the differential processing of their products probably have biological significance. Indeed, differential expression of mammalian enolase isoproteins has been observed

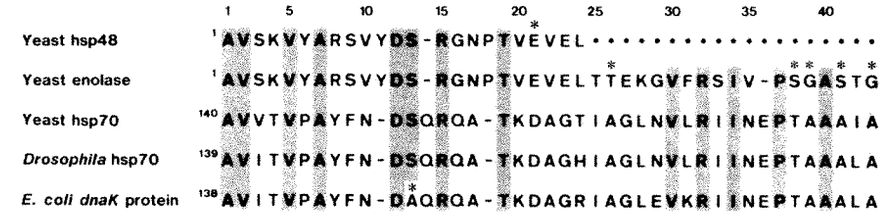

Fig. 2 Comparison of amino-acid sequences of HSP48, yeast enolase and possibly related heat-shock proteins. The sequences of yeast HSP48 (residues 1–23), yeast enolase (Residues 1–41)[12], yeast HSP70 (the *YG100* gene product, residues 140–180)[27], *Drosophila* HSP70 (residues 139–179)[28] and *E. coli dnaK* protein (residues 138–178)[13] are aligned to show the maximum homology among these proteins. Numbers on the left indicate the position of the residue in the molecule. Shading indicates homology. Asterisks indicate conservative amino-acid substitutions as defined by Schwartz and Dayhoff[29]. Dots indicate residues which have not been experimentally determined. − Indicates a space added to maximize the homology.

Methods. An aliquot of purified HSP48 was dialysed against 1 mM ammonium bicarbonate, lyophilized and dissolved in 1% trifluoroacetic acid. Amino-acid sequence results were obtained by using a protein sequencer (Model 470A; Applied Biosystems).

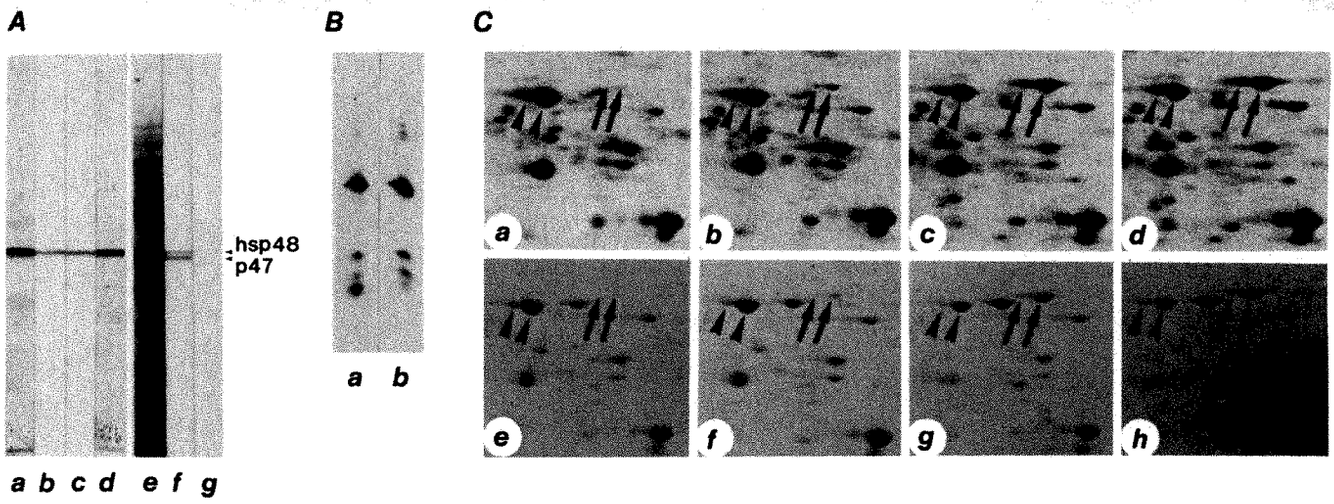

Fig. 3 *A*, Immune blotting of yeast whole-cell extracts and authentic yeast enolase with anti-yeast HSP48 antibody. Purified HSP48 (lanes *a*, *b*), yeast enolase (lanes *c*, *d*) and extracts of X2180-1A cells in the stationary phase (lanes *e*–*g*) were resolved in SDS-PAGE and electrophoretically transferred to a nitrocellulose sheet. The sheet was stripped and strips were separately incubated with 1:500 diluted rabbit yeast anti-HSP48 antiserum (lanes *b*, *c*, *f*) and preimmune rabbit serum (lane *g*), followed by incubation with peroxidase-conjugated goat anti-rabbit IgG (Cappel). A strip was stained with Auro Dye (Janssen) (lanes *a*, *d*, *e*). ***B***, Peptide mapping of HSP48 and p47. The spots of ^{35}S-methionine-labelled HSP48 (lane *a*) and p47 (lane *b*) were subjected to peptide mapping with *S. aureus* V8 protease as described in Fig. 1 legend. ***C***, synthesis rate and content of HSP48 and p47 in heat-shocked or G_0-arrested yeast cells. *a*, *e*, Exponentially growing X2180-1A cells at 23 °C in synthetic complete medium; *b*, *f*, heat-shocked cells at 36 °C for 1 h; *c*, *g*, cells kept in stationary phase for 24 h; *d*, *h*, cells starved of sulphur for 24 h by incubation in sulphur-free medium[8]. The cells in each of the above cultures were pulse-labelled with ^{35}S-methionine and chased as described in Fig. 1 legend. The whole proteins (25 μg each) extracted from these labelled cells were analysed in two-dimensional gel electrophoresis as described for Fig. 1. Protein spots were revealed by autoradiography (*a*–*d*) and staining (*e*–*h*). A pair of arrowheads indicate p47A (left; acidic form) and p47B (right; basic form). A pair of arrows indicate HSP48A (left) and HSP48B (right).

during differentiation and maturation of neurones and teratocarcinoma and neuroblastoma cell lines[15–18].

The expression of the enolase genes seems to be regulated by many systems. First, it depends on carbon sources in the media[14]. Second, we have shown previously that the *HSR1* gene negatively regulates the synthesis of six proteins—HSP48A, HSP48B, two G_0-induced proteins (p73 and p56) and two unidentified proteins (p63 and p60)[8]. Third, exposure of *HSR1* cells to mild heat shock increases the synthesis rates of the two HSP48s and of other HSPs[7]. Finally, *hsr1* cells starved of sulphur or arrested in the stationary phase synthesize HSP48A, HSP48B, p73 and p56 at higher rates than do exponentially growing *hsr1* cells[8]. These results suggest that the synthesis rate of HSP48 (enolase 1) is affected by at least three factors, the *HSR1* gene, growth conditions and heat shock, although these factors may partly overlap. In agreement with our results, McAlister and Holland have noted that the content of enolase 1, but not of enolase 2, is significantly increased in yeast cells grown to the stationary phase[14].

Finally, the question arises of whether HSP48 functions solely as a glycolytic enzyme when it is involved in growth control and in protecting yeast cells from lethal heat shock. The synthesis of other glycolytic enzymes linked to enolase, such as glyceraldehyde 3-phosphate dehydrogenase or pyruvate kinase, is not significantly altered in *hsr1* cells or when *HSR1* cells are preheated by 36 °C (ref. 19 and our unpublished observation). This result is consistent with the hypothesis that the heat-shock resistance acquired by the *hsr1* mutation and heat pretreatment may be ascribed to some function associated with HSP48 other than enolase activity. Analysis of the intracellular distribution and molecular interactions of HSP48 (enolase 1) with other molecules, especially in comparison with p47 (enolase 2), should provide more direct evidence.

We thank Drs Hiroshi Kawasaki and Koichi Suzuki for amino-acid sequencing, Ms Yoko Nadaoka and Dr Tsuguchika Kaminuma for analysis of the protein sequence bank, and Dr Kazuko Iida for immune blotting. This work was supported in part by Grants-in-Aid from the Ministry of Education, Science and Culture of Japan.

Retroviral protease-like sequence in the yeast transposon Ty*1*

RECENTLY, Mellor *et al.*[1] determined the nucleotide sequence of the 5'-terminal portion of the yeast transposon Ty*1* and identified two open reading frames, ORF1 and ORF2, which are in the same relative positions as the *gag* and *pol* coding sequences in retroviruses. In addition, they showed that Ty*1* produces a fusion protein by a specific frameshifting process similar to that used by retroviruses. We have shown that retroviruses, cauliflower mosaic virus (CaMV), *Drosophila copia*-like element 17.6 and Syrian hamster intracisternal A-type particle (IAP) contain sequences homologous to the *gag*-specific protease p15 of Rous sarcoma virus (RSV) in the same relative positions[2,3]. Furthermore, these p15-related sequences contain a highly conserved stretch of amino acids which shows a close similarity with sequences around the active-site amino acids Asp-Thr-Gly of the acid protease family, suggesting that they possess a similar activity to that of acid proteases[2].

A computer-assisted search for homology has revealed the presence of the p15-related sequence in the ORF2 of Ty*1* (Fig. 1, Table 1). Thus, the N-terminal portion of the ORF2 product may have an activity similar to that of acid proteases. Such a widespread occurrence of the protease sequence suggests that it is vital for these viruses and transposons. Mellor *et al.* suggested that the fusion protein is processed proteolytically[1]; the ORF2-coded protease may be involved in this processing. The relative positions of the conserved segments are almost the same among Ty*1*, CaMV, 17.6 and Moloney murine leukaemia virus (M-MuLV) (Fig. 1), suggesting that the observed homologies are the result of divergence, not convergence. This also supports the notion that the ORF2 corresponds to *pol* in retroviruses[1], and thus the reverse transcriptase coding sequence, which is highly homologous among reverse transcriptase-containing viruses and transposons[2-5], probably lies in a region immediately downstream from the protease region.

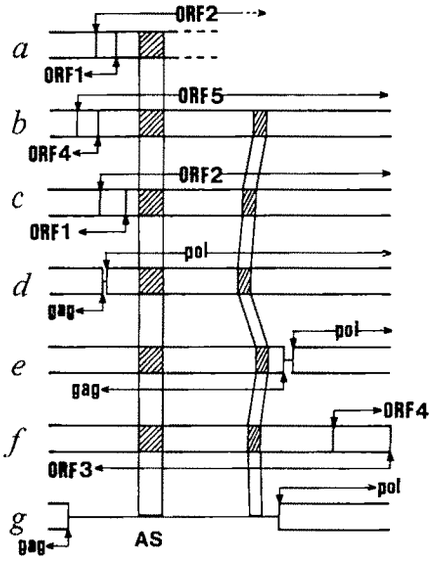

Fig. 1 Maps of homology between protease regions of reverse transcriptase-containing viruses and transposons: *a*, Ty*1*, *b*, CaMV; *c*, 17 6; *d*, M-MuLV, *e*, RSV; *f*, IAP; *g*, HTLV-I (human adult T-cell leukaemia virus). Homologous segments are linked by slanted lines. No open reading frames are assigned between *gag* and *pol* in HTLV-I. Data were taken from ref 2 for *b–e* and *g*, and from ref. 3 for *f*. AS, the region showing a close sequence similarity with active-site amino acids of the acid protease family

Table 1 Amino-acid sequence comparison between p15-related proteases and pepsin-related acid proteases

Viral protease	
Ty*1* ORF2	GHLLL-DSGASRTLIRS
CaMV ORF5	LHCFV-DTGASLCIA-S
17.6 ORF2	LKCLI-DTGSTVNMT-S
M-MuLV *pol*	VTFLV-DTGAQHSVL-T
RSV *gag* p15	ITALL-DSGADITII-S
IAP ORF3	FEGIM-DSGADKSII-S
HTLV (*gag-pol*)	IEALL-DTGADMTVL-P
	*
Acid protease (C-terminal)	
Pepsinogen (human)	CQAIV-DTGTSLLTG-P
(porcine)	CQAIV-DTGTSLLTG-P
Prochymosin (bovine)	CQAIL-DTGTSKLVG-P
Penicillopepsin	FSGIA-DTGTTLLLL-B
Renin (mouse)	CEVVV-DTGSSFISA-P
(human)	CLALV-DTGASYISG-S
	*
Acid protease (N-terminal)	
Pepsinogen (human)	DFTVVFDTGSSNLWV-P
(bovine)	DFTVIFDTGSSNLWV-P
(porcine)	DFTVIFDTGSSNLWV-P
Prochymosin (bovine)	EFTVLFDTGSSDFWV-P
Penicillopepsin	TLNLNFDTGSADLWV-F
Renin (mouse)	TFKVMFDTGSANLWV-P
(human)	TFKVVFDTGSSNVWV-P

As pepsin-related proteases consist of two topologically similar domains and two active-site aspartic acids, the amino-acid sequences around the two active sites were aligned between the N- and C-terminal halves. Bold type indicates amino acids that are identical or chemically similar among 18 sequences (90%) out of 20 at each position. Gaps(-) were inserted to increase sequence similarity. * Active sites of acid protease family For sequence data, see refs 2 and 3.

MELLOR *ET AL* REPLY—WE thank Toh *et al.* for their interest in our paper[1] and for pointing out the homology with acid proteases at the beginning of ORF2 in Ty*1-15*. We would like to add that in pulse-chase experiments the protein, p1(Ty1-15), encoded by ORF1 in Ty*1-15* seems to be processed, presumably by proteolytic cleavage. Furthermore, we have recently identified a candidate for the 'natural' product of ORF1/ORF2 fusion. This protein, p3(Ty1-15), has a relative molecular mass of 190,000 and can be seen only in short pulse-labelling experiments. Like p1(Ty1-15), therefore, it also appears to be proteolytically cleaved. We have observed four possible cleavage products and their relationships with p1(Ty1-15) and p3(Ty1-15) are presently being established. The 'processing' of p1(Ty1-15) is dependent on the expression of ORF2, a result that is consistent with the processing protease being encoded within this region and therefore in agreement with the

observations of Toh *et al.* The interrelationships of Ty proteins will be reported elsewhere[2].

Forest succession

MOST forest ecologists will agree with the conclusion of Finegan[1] that in real forests, succession commonly has characteristics of both the contrasting models he has described: a 'holistic' facilitation model where successive species replace each other and a 'reductionist' model where all species arrive at the outset.

Finegan is wrong, however, to say that no direct studies have been made of forest succession. Many studies do indeed rely on contemporaneous observations of forest patches of purportedly known age and history, but in the Eastern tropical rainforests there have been four studies of forest patches through time which clearly illustrate various departures from the two paradigms These studies, originally reported in the specialist forestry literature, were used in the analysis of dynamic processes in a general account of the Eastern rainforests[2].

At Kepong, Malaysia, forest on an abandoned field has been monitored since 1947[3]. Here, the flora changed little between 1949 and 1960 because of a fern blanket, which was eventually shaded out, so from 1960 to 1976 there was a marked change, though climax species were still scarce. At Sungai Kroh, Malaysia, a similar succession was monitored for 17 years from 1946 to 1963[4]. Here, some tree species, including the dominant species, were present throughout while others progressively arrived. No fern blanket developed. At Sungai Menyala, Malaysia, a secondary forest established in 1917 has been monitored since 1947[2,5]; here spasmodic floristic change is still occurring. After natural catastrophic destruction by repeated cyclones, succession at Kolombangara in the Solomon Islands has been under observation since 1964, and analysed for the first 6.6 years[2,6]. The latter two studies also include areas of 'climax' forest which are showing 'cyclic replacement'[7] (rather than 'directional change in time' as Finegan[1] defines succession) much more rapid than suggested by conventional wisdom about the stability of primary equatorial forests. Finegan excluded cyclic replacement from his discussion. It does not involve directional change in time and is the process whereby climax ecosystems are maintained in the absence of catastrophic destruction. (The latter is followed by 'secondary' succession (as it is usually termed) back to climax.) Cyclic replacement is occurring at Sungai Menyala.

At Kolombangara island, the north-coast forests are believed to be repeatedly destroyed by cyclones; they show succession as discussed by Finegan. The west-coast forests, by contrast, are outside the influence of cyclones and show cyclic replacement Sungai Menyala and Kolombangara demonstrate the value of long-term studies, and in fact these studies have continued longer than any others in climax tropical forest. The Kolombangara study includes the monitoring of recruitment, growth and mortality of seedlings of the 12 main large tree species and how these are influenced by different amounts of leafy canopy overlying them. For these species the total population is being monitored and the resultant understanding of their autecology has aided the analysis of the contrasting dynamics of successional (north-coast) forests and cyclically replacing (west-coast) forests. So far, nine sets of observations over 6.6 years have been analysed, and a further analysis is planned to start in 1986, covering another three sets of observations to 21 years. Both the Kolombangara and Sungai Menyala forests are under threat of conversion to more lucrative land-use, the much-discussed fate of many tropical rainforests, despite the contribution they have made to ecological understanding of forests[2,8-11], which itself underpins silviculture. The longer the studies continue, the more they reveal.

FINEGAN REPLIES—I thank Whitmore for pointing out this gap in my review[1]. The studies he cites are interesting and illuminating and deserve a wider audience (although I was unable to find Whitmore's ref. 5 and am unable to comment on it)

One point concerning long-term studies is worth making here. Two of those cited by Whitmore[2,3] provide structural and floristic description only, and therefore cast very little light on the mechanisms of the successions which are clearly occurring. Measures of species abundance against time can be used to support almost any mechanistic model of succession, from the initial floristic composition ideal to a number of composite processes, as shown in my Fig. 4[1]. No amount of description, whether inferred or obtained directly, will overcome this problem; hence the last paragraph of the review. Whitmore's studies at Kolombangara exemplify the sort of approach which is needed[4].

I did not discuss cyclic replacement because there is a clear ecological basis for separating this process from the successions I review, involving differences in initial environmental conditions and sources of colonizing individuals. As Whitmore himself has pointed out, pioneer trees participate only infrequently in cyclic replacement patterns[4,5]. I should have restricted my formal definition of succession by referring to processes occurring in cleared areas large enough to permit the establishment of a vegetation dominated physiognomically by pioneer trees.

Matters Arising

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted. Neither contribution nor reply (if one is necessary) should be longer than 500 words and the briefest of replies, to the effect that a point is taken, should be considered.

ALTERNATIVE IMMUNOASSAYS

edited by **W.P. Collins,** *Department of Obstetrics and Gynaecology, King's College Hospital Medical School, London*

Recent advances in biotechnology are changing the study and practice of diagnostic medicine, and have lead to a revival of interest in alternative immunoassays. This situation is mainly due to the advent of monoclonal antibodies, and the use of alternative labels to monitor the reactions. This book is a comprehensive review of the new concepts, developments and applications of alternative immunoassays written by experts in the field. Different assay systems are described using monoclonal, oligoclonal or polyclonal antibodies, in the context of alternative solid phases, end points (visual or quantitative) and instrumentation (for example, radioluminometry, spectrophotometry and time-resolved fluorometry).

ANTIFIBRINOLYTIC DRUGS Chemistry, Pharmacology and Clinical Usage

by **D. Ogston,** *Department of Medicine, University of Aberdeen*

Drugs which inhibit the action of the fibrinolytic system have been available for around twenty-five years. Initial enthusiasm for their use in the management of bleeding (both generalized and local) and a wide variety of other conditions, has been replaced by a more critical assessment of their therapeutic indications. This volume reviews the accumulated knowledge of the chemistry and pharmacology of the antifibrinolytic drugs and describes their past and present clinical usage, with particular reference to the information gained from controlled clinical trials.

THE LUTEAL PHASE

edited by **S.L. Jeffcoate,** *Department of Biochemical Endocrinology, Chelsea Hospital for Women, London*

The luteal phase is the time after ovulation, when the steroid hormones from the corpus luteum prepare the uterine endometrium to receive and nurture a blastocyst. This volume thus carries on from the point where the previous volume in the series — on follicular development and ovulation — ended. As in previous books in the series, the physiological and biochemical background is covered in the early chapters. Later chapters deal with abnormalities of the luteal phase and infertility; finally, current approaches to contraception in the luteal phase are described.

Wiley series on Current Topics in Reproductive Endocrinology, Volume 4.

ANTICOAGULANTS AND MYOCARDIAL INFARCTION A Reappraisal

edited by **T.W. Meade,** *MRC Epidemiology and Medical Care Unit, Northwick Park Hospital, Harrow*

The main purpose of this book is to review the evidence on the use of anticoagulants. This evidence — pathological, clinical and epidemiological — is complemented by accounts of the biochemistry of the coagulation system, and of the pharmacology of anticoagulants. The book identifies the issues which are still not fully resolved, and the topics which many of the experts in the field continue to debate. This book should be viewed not as a comprehensive handbook of anticoagulant treatment (though several chapters naturally deal with issues which frequently arise in clinical practice) but rather as a summary of the new information which justifies a reappraisal of the whole.

0471 90442 2 284pp November'84 £28.50

SCREENING AND MONITORING OF CANCER

edited by **B.A. Stoll,** *St Thomas' Hospital and Royal Free Hospital, London*

Recent advances in the diagnosis of malignant and premalignant lesions include the use of biological and biochemical markers, new imaging techniques, greater resolution of chemical change in tissue, and improved techniques in cytological and nucleoprotein measurement. This book aims to evaluate the likely impact of these new developments on screening and monitoring in solid cancer, and to set out the current state of the art. It contains a great deal of information on the subject of cancer screening and monitoring, much of which would otherwise be very difficult to locate because of its diverse nature. It provides an up-to-date and detailed overview of the subject for all clinicians involved in the management of cancer patients.

Wiley series on New Horizons in Oncology, Volume 4.

Thinking about thinking

Duncan Davies

Science as a Commodity: Threats to the Open Community of Scholars.
Edited by Michael Gibbons and Bjorn Wittrock
Longman 1985 Pp 173. Pbk £9.95, $15

"SHOULD university teachers or researchers display patriotism by undertaking work for the armed forces which will inevitably be secret and unpublishable?". "Should they help pay for their institutions in hard times by making contracts with industrial firms whereby publication of research must be delayed, perhaps for a year or two, until intellectual property rights have been safeguarded by patents?". "Is public funding of university work best guided by simply choosing the best men, and leaving them to choose their research topics as best they can?". "Would the best women, if so funded, choose differently from the best men?". "For such privileges, who are the best people and how do you choose them?".

These are good questions, the resolution of which is of great importance for the maintenance of democracy and survival of freedom of inquiry and speech. It is therefore eminently reasonable to convene a conference to discuss them in detail. One would invite people from a cross-section of backgrounds university teachers currently doing research in the humanities, engineering and science (and, if possible, across more than one field), practising men of business and public affairs; and some military people, to relate their problems and experiences. One would cover diplomacy, matters of public order, economics, investment, taxation and technology, with science and philosophy bulking large in the background. There would doubtless be difficulties of language and psychology, and many important differences in priorities and chosen compromises, but the result would be very fruitful.

Conversely, it might seem one-sided to conduct such a conference in the virtual absence of the practitioners of science, and to publish essays only by (admittedly able and clever) university teachers whose specialism is mainly the study of those who study engineering and science, in the absence of practitioners of finance, law, psychology and medicine. And it might seem confusing to use the title *Science as a Commodity*

There used to be a gibe that you could always find the Germans in a crowd by inviting everyone to choose between two doors marked "Heaven" and "Lectures on Heaven". Excessive specialist theorizing is now spread throughout the Anglo-Saxon world, to the extent that it is no longer fair to pick on the Germans Those of us who have worked hard to encourage interest in broader matters in the choice, conduct and exploitation of research, feel a little frustrated because success in drawing attention to this synthesis has created another band of specialists, engaged not in practice, but only in a new branch of theory

There are wise thoughts in this book, the published record of the meeting, but there is also an overdose of theology, and repetitious concern with a few causes célèbres (such as Faust, Bacon, the Manhattan Project — described rather inaccurately by one of the contributors — and the arrangements between Hoechst and Mr Whitehead on the one hand, and the universities in Boston, Massachusetts, on the other) And there is very little about the actual products, processes and services which most illuminate the connection between free inquiry and practical application (or, which comes first), or whether the great increase in society's investment in technology seems to have helped or hindered such basic research as the astronomical study of the Universe, its cosmological interpretation, the structure of matter and energy, and the origins of life and inheritance. It may be that the practical men (inside and outside the universities) were in fact invited but would not come; if so, their contributions should have been sought by other means, and not beaten into shape with theory.

The unconfused title for the book could well be *Technology as a Tradeable Investment* or *Should Scientists do Secret Military Research?*, but these would not sound sufficiently mysterious and profound Professor Wittrock, in his summing up on p. 156, says "Science has not become a commodity; it always was". Professor Salomon, on p. 78, says "Science as a commodity? Only half a century ago, such a question would have appeared as a provocation, and a century ago, as an aberration". This apparent disagreement between gurus stems, of course, from different interpretations of the word "science", and the problem is intensified for two other reasons: first, the words science, technology and research are repeatedly used interchangeably. Secondly, in this context the term "commodity" is less appropriate than the term "investment". The trading of investments is a rather different process from trading in consumer goods. Technology, rather than science or research, is our most comprehensible kind of intellectual investment. It has been traded always, but most particularly since the patent system was introduced four centuries ago to *prevent* (not assist) secret operation; the method was the award of a temporary monopoly in return for disclosure, to allow the recoupment of the investment cost Inventive applied science can sometimes be traded as a component of technology, but the ways of nature cannot be closed to astronomers, high-energy physicists or geneticists. These subjects can be kept secret only for as long as there is military control over the instruments needed for the work (rockets to launch the satellite: detectors to measure the radiation). By contrast a commercial firm would want to go public and sell the gear

So the real problem is that of the *military* restraint of the dissemination of *technology*, with its attendant economic penalty for all, and not that of the selling of university science by commercial interests. Commerce requires the most temporary protection of knowledge that will make long-term research and development worth while, and the earliest practicable publication Men of good will such as Sir Cyril Hinshelwood, President of the Royal Society from 1955 to 1960, regarded applied research, of whatever kind, as one of the most valuable sources of ideas for scientific discovery, they sought to participate in both discovery and invention. When military secrecy hindered this natural exchange, they sought means for distilling the clues for science into publishable form.

Once this confusion is cleared up, the book becomes a useful quarry with some interesting thoughts on a variety of matters. For instance it is hard not to agree with Helga Nowotny that women would choose different research topics from men, and hard not to conclude that both science and technology are impoverished by the small number of influential women involved. But the real need is for much more study of individual examples, for example to help decide whether peacetime science and the technology-based business that funds it depends heavily, lightly or not at all on science conducted for military purposes. Did polythene, radar and the gas turbine (all invented in peacetime) require wartime funding to reach peacetime use? Was anything at all invented in wartime, does war merely accelerate and enable the development of peacetime ideas that were languishing? More broadly, would cephalosporin have been discovered by a firm, and could the semi-synthetic penicillins have been developed in a university? More pragmatism, please, before the next bout of analysis □

Awash in an ocean of information

David Smythe

The Geology of the Atlantic Ocean.
By K. O. Emery and Elazar Uchupi.
Springer-Verlag 1984 Pp 1,050 DM 360, $104.80.

THE Atlantic Ocean has grown a few centimetres wider in the past few years. It has also undergone a change in location. The North Atlantic is nowadays thought of as the segment between Europe and Greenland, and the Africa – North-America segment is now the Central Atlantic. The South Atlantic remains as before, between Africa and South America. This sensible shift in nomenclature avoids such possible infelicities as "southern Central North Atlantic", or even "northern Northern North Atlantic". Emery and Uchupi's encyclopaedic compilation, some eight years in the making, sticks to the older (oceanographic) rather than the new (plate tectonic) Atlantic, and barely reaches Iceland. The book is therefore incomplete, which is a pity; many of the current problems in understanding the complex plate history north of 50°N or so have arisen through an artificial division of expertise and interest north and south, respectively, of the Greenland–Scotland Ridge.

Eleven pairs of large, loose-leaf charts cover the region 60°N to 60°S They include bathymetric, physiographic, sediment isopach, and tectonic maps Each chapter is ocean-wide in scope, ranging from history, through physiography, geology and evolution, to a final chapter on geography and economics, including waste disposal and hydrocarbons. The most up-to-date and comprehensive of them are the accounts of syn-rift and drift sediments — subjects on which the authors are long-established authorities. These chapters, making up some 40 per cent of the book, draw upon many references of 1980–1983 vintage, and take advantage of good-quality reproduction or re-drawing of original figures.

Where the discussion strays beyond the book's title — both sideways and downwards — I have increasing reservations. Some sections have a definite air of obsolescence. Why, for example, write about the North Sea at all if you have to lean heavily on review papers, one or two of which were mediocre even when they were read at the first major conference on the North Sea in 1974? Why try to write about the Neolithic and Early Bronze Age sailors of north-west Europe (incorrectly referred to as Celts) if you neglect their knowledge of navigation? They were able to predict complex lunar motions and presumably, therefore, the powerful Atlantic tides on which their maritime civilization depended. The North Sea has become a mature oil province since the early 1970s, and in the same period the whole new science of archaeoastronomy has blossomed

The chapter on internal igneous structure begins at the core and works upwards through geomagnetism, the mantle, heat flow and seismicity, petrology and so on to the ocean crust itself. On the way up there is a short excursion to the Moon. The heart of the subject — the structure, petrology and magnetic properties of oceanic crust — is dealt with in rather cursory manner; for example, there are no diagrams here showing the great variety of evolutionary models that have been thought up for the basaltic Layer 2

Even more unfortunately, an important section on the geomagnetic polarity reversal timescale picks upon one of the least satisfactory revisions for the late Mesozoic and Cenozoic, which was published in 1980. An entire industry of reversal timescale "improvements" has sprung up in the United States in the past few years, but Emery and Uchupi perpetuate an inexplicable omission by the specialists of any reference to the superb work of Hailwood and co-authors, which appeared in the Initial Reports of the Deep Sea Drilling Project in 1979 — hardly an obscure source. Six years ago you could have taken Hailwood's scale, added it to the Gubbio timescale for the late Cretaceous, run it through a pocket calculator to update the radiometric decay constants, and you would have had a "working" timescale for the past 100 million years or so, essentially as good as any of today's efforts. The moral of this example seems to be that you have to publish loud, fast and often in order to get cited, which will merely hasten the day when we are all drowned by the rising sea-level of publications.

Emery and Uchupi have obviously had difficulty in keeping their ambitious project watertight in the decade since they laid its keel. Although they have made a valiant effort, I think that the scope of the subject, at least in the terms that they see it, is now simply too broad for any two people to tackle successfully. □

David Smythe is a Principal Scientific Officer at the British Geological Survey in Edinburgh.

New journals review

On 26 September *Nature* will publish the fifth annual review supplement devoted to science journals Publishers and learned societies wishing to submit material should refer to last week's issue of *Nature* (p 607) or contact the Book Review Editor (London 836 6633)

BWP four

John Andrews

Handbook of the Birds of Europe, the Middle East and North Africa. The Birds of Western Palearctic. Vol.IV: Terns to Woodpeckers.
Chief editor Stanley Cramp.
Oxford University Press: 1985.
Pp.960 £60.

THE latest volume of "BWP", as it has come to be known, describes a further 113 species of birds from the 760 or so which occur in the Western Palearctic. Commencing with the terns, skimmers and auks, it progresses through sandgrouse, pigeons and parrots — whose sole representative is the introduced ring-necked parakeet — to cuckoos, owls, nightjars, swifts, kingfishers, bee-eaters, roller and hoopoe, concluding with the woodpeckers.

Each species entry runs to about 6,000 words. As well as giving field identification characteristics, it provides detailed descriptions of plumages necessary for the identification of specimens in the absence of reference skins, and data on moult measurements, weights, structure and geographical variation. The colour plates, all of them by artists with field experience of most if not all of the subject genera, show the main plumages, including downy young (and eggs) with an acceptable consistency of style.

Once the text moves on to material derived from research it is inevitably more varied in quality and comprehensiveness. The habitat descriptions enable one to look for a given bird in the right place but are often insufficient, even when considered together with information on food, to guide either habitat management or conservation judgements on the implications of subtle changes in land use. In general, more is known of breeding requirements than of wintering habitat usage, and that too is reflected in the book.

Distribution maps show separately the world and Western Palearctic ranges, while the text concentrates upon historic changes in range (which yet often remain inexplicable). Population size is usually based on national estimates, which are notoriously questionable.

The bulk of the text is devoted to social patterns and behaviour, and breeding biology. In bringing together all of this material, the book — and the series — has value not only in its own right but as a basis for comparison which may in time extend our knowledge of "why" as well as "what". By implication, this massive and invaluable exercise in ornithological publication raises the question of whether the work should be allowed to end with the appearance of each volume or whether some continuing process of updating is practicable and worthwhile. □

John Andrews is Head of Conservation Planning at the Royal Society for the Protection of Birds, Sandy, Bedfordshire

Culture of genetics

Peter Goodfellow

Mammalian Cell Genetics.
By Martin L. Hooper.
Wiley: 1985 Pp.175. £63.25, $49.95.

AT THE same time as the molecular revolution in genetics, a quieter revolution has occurred in the genetics of cultured cells. Older techniques, such as variant isolation and production of somatic cell hybrids, have been improved and supplemented with methods such as DNA-mediated gene transfer, expression of bacterial genes in mammalian cells, microcell transfer of chromosomes and chromosome-mediated transfer of sub-chromosomal fragments. In *Mammalian Cell Genetics* Dr Hooper has provided a commentary on the whole of modern somatic cell genetics, designed to be read in conjunction with the primary literature.

Guides such as this can either be Talmudic, expanding and clarifying an obscure text or, like the synopsis of an opera, condense the story while emphasizing the highlights. By the author's stated intention, the book falls into the latter category. It does not purport to tell you how to do an experiment but informs you of the experiments that have been done. As such it will provide novices with an overview of the possibilities available before they delve into more specialist publications.

A good commentary should be comprehensive and emphasize the right points. *Mammalian Cell Genetics* is comprehensive for techniques up to 1983, but the tables of cell lines available should not be regarded as exhaustive and events of the past two years have somewhat overtaken the tables of molecular vectors The choice of highlights is more open to argument and largely a matter of personal opinion. I would have emphasized human gene mapping, monoclonal antibodies and isolation of oncogenes by DNA transformation of cultured cells. Perhaps as a consequence of his apparent determination to be succinct, Dr Hooper treats the first two of these achievements as derivatives of the esoteric, and often arcane, truths of chromosomal segregation and extinction of "luxury" functions in hybrid cells. Formally he is correct, but, for me, it counts as a failing. Limitations on length probably also explain the absence of some essential practical details, such as the amount of transforming DNA a mammalian cell can take up and incorporate into its genome or the maximum size of individual DNA molecules which can be incorporated. Also missing is debate about the major unsolved problems in mammalian cell genetics; for example, many people would like to obtain homologous recombination between exogenously introduced DNA and the equivalent recipient cell gene.

The book is a helpful guide and any postgraduate student of mammalian genetics would benefit from reading it. Unfortunately, the absurd price means that our hypothetical student will either have to spend a week's wages or read somebody else's copy. I would suggest the second alternative. □

Peter Goodfellow is Head of the Human Molecular Genetics Laboratory at the Imperial Cancer Research Fund Laboratories, London

Colourful behaviour

M. E. G. Evans

Insects in Camera.
By Christopher O'Toole.
Oxford University Press: 1985. Pp. 154. £14.95, $29.95.

THIS is not just another book of pretty pictures of animals. Rather, it is a collection of superb colour photographs by Ken Preston-Mafham in which are captured the behaviour of living insects. Christopher O'Toole's text introduces and explains the photographs so that we have a rather unusual combination of linked illustrations and text, describing not merely a series of insect types but their great diversity of behaviour patterns.

The question posed is "How are insects adapted to survive in a hostile world?" The answer, of course, is "very well", but this book delves into the underlying reasons. There are seven sections, each of which is introduced by a short essay. The rest of the text consists of long legends to each of the photographs, in which the species and their systematic positions are noted, and their activities described. The photographs are not just of insects seen against typical backgrounds; some are unique, for instance the picture of a hovering muscid fly introducing her offspring into driver ant society by the precision bombing of an ant column with her eggs.

A disadvantage of breaking up the text into a series of short paragraphs is that the book is necessarily somewhat fragmented; there are nearly as many stories as there are pictures. However, my main criticism is that where there are three or four prints to a page the detail cannot be appreciated. I would have preferred none of the photographs to have been less than half-page size, even at the price of fewer of them. Nevertheless, this is a stimulating account of insect behaviour and adaptation, with an intelligent text elaborating upon the excellent pictures. For many readers it will be literally an eye-opener. □

Personal atmosphere for the physicist

J. R. Milford

Physical Meteorology.
By Henry G. Houghton.
MIT Press 1985 Pp.442. $37.50 £41.95.

FOR Professor Henry Houghton's colleagues and former students the publication of *Physical Meteorology* will be an event of some note It will also enable a much wider range of atmospheric physicists to benefit from his wisdom The qualities of a great teacher shine through this book, with scholarship, clarity of argument, enthusiasm and a welcome readiness to discuss points of uncertainty. He is also ready to say when an exact theory is inapplicable to a real, untidy atmosphere, for instance when we consider the scattering of radiation.

The use of the book as a text to support other people's courses will be restricted, however, by a number of its characteristics. First, it is only for competent physicists, assuming as it does some prior knowledge of Raman scattering, or of what is meant by local thermodynamic equilibrium, to give just two examples. Secondly, the choice of material is very personal, as indeed is made clear in the preface. The main sections consist of four chapters on radiation in the atmosphere and three on cloud physics these are preceded by an opening chapter on the atmospheric aerosol This is logical enough, but there is only minimal explanation as to how this information may be used later in the book and there are in fact few references back to it. The final chapters on optical phenomena and atmospheric electricity are also self-contained

The book thus covers the topics which are traditional in texts on atmospheric physics Professor Houghton admits to doubts on the title, and it seems to me that *Physical Meteorology* is now a misnomer: operational meteorologists will not find much of the theory behind their practice here. The turbulent transfers of energy which bulk large in much of our science find no mention, and surely the links with large-scale energetics merit discussion if meteorology is included in the title?

In smaller matters the choice of material is again unashamedly (and excusably) personal. However, more applications of the existing material could have been included: illustrations of scattering or anomalous propagation of radar would have helped readers to make links with specialist studies without any risk of trespassing on them. The relevance of the radiation chapters to remote sensing could have been brought out too, in contexts other than temperature sensing with the 15μm CO_2 band Even in this section the paragraph on the non-American method is so brief as to be quite unhelpful.

Textbooks which include problems at the end of each chapter are always attractive to other teachers, but those included here are less useful than some since they are mainly designed to stimulate open-ended discussions. They provide no help to the struggling lecturer who needs to know whether he has got it right

As I read the book I was occasionally irritated by misprints, and, more often, by the adherence to old-fashioned units, even when a change would be trivial: why not replace $°C^{-1}$ by K^{-1}? Also, the basic radiation and derivations are not entirely clear, mainly due to Professor Houghton's refusal to use the term "radiance" Some diagrams raise questions I would like answered, such as Fig 7.14 which includes collision efficiencies for drops rising to a value of ten in a very curious fashion. But one should not be put off by such deterrents, or by the absence of references after 1980, for here there is much insight and illumination of the principal parts of atmospheric science □

Psychological notes

Eric Clarke

The Musical Mind: The Cognitive Psychology of Music.
By John A. Sloboda.
Clarendon: 1985. Pp.291. £20.

THE power of music to move people's minds, and the ability of a few minds to produce performances and compositions of great profundity, have raised questions that can be traced from Plato's *Republic* to the current Oscar-award-winning film *Amadeus*. Since the beginnings of modern psychology they have also been a focus of attention for those attempting to understand musical cognition with more rigorous methods. Until recently the psychology of music could not claim to be a major area of research, but two new journals on the subject and a steady stream of books and articles indicate that this is changing.

Most of the literature has, however, held more interest for the experimental psychologist than for the musician, concerned as it is with highly reduced "musical" materials investigated under extremely constrained (and unmusical) conditions. It is therefore a breakthrough that a book has now appeared which brings together recent work in a way that demonstrates its significance for musicians, whilst in no way compromising the psychological theory on which it is based.

In the preface to *The Musical Mind*, John Sloboda makes it plain that the primary aim of his book is to bridge this gap, and he is to be congratulated on doing so. Sloboda's cognitive approach, and his desire to address matters that preoccupy musicians, have resulted in a book that covers many areas usually absent from writings on the psychology of music. Thus while there is a substantial chapter on listening to music, there are also accounts of musical learning and development, musical performance, and composition and improvisation. The section on composition is an excellent attempt to unravel the psychological processes involved in this least-understood area of musical cognition, using the compositional sketches of various composers (Beethoven, Mozart, Stravinsky), and the written accounts of Sloboda's (and another composer's) compositional methods. It is Sloboda's willingness to make use of evidence from a wide variety of sources that allows him to delve into areas previously considered too private to be investigated, and which brings an engaging freshness to the book.

Besides these four chapters, the book is outstanding for the subjects treated in the second and last chapters — music, language and meaning, and music, culture and biology, respectively. The second chapter draws together some of the recent thinking on the formal similarities between music and language, and considers the psychological processes that they may share. The last chapter, which looks at the psychological issues raised by cross-cultural studies of music, and examines the neurological and broader biological bases for music, is an important reminder of how ethnocentric most work on the psychology of music is, and of the insights to be gained by widening the cultural perspective.

There are some weaknesses: the comparison of the work of the linguist Chomsky and the musicologist Schenker is too simplistic; the discussion of musical meaning is taken less far than it might have been; and a consideration of the psychological questions stemming from developments in contemporary music would have been welcome. But the clarity of Sloboda's writing and his numerous suggestions for further research will make his book essential reading for anyone, student or researcher, interested in how minds and music interact. □

THE FISCHER-TROPSCH SYNTHESIS
ROBERT B ANDERSON
With a Chapter by Professors H KOLBEL and M RALEK

The Fischer-Tropsch Synthesis provides a comprehensive account of the catalysts, kinetics, and reaction mechanisms of the Fischer-Tropsch Synthesis (FTS) Literature discussed in the book includes pertinent papers from 1955 through 1983, reviewed by a chemist with nearly forty years of experience with FTS

A well-detailed and comprehensive volume, *The Fischer-Tropsch Synthesis* will be of great value to companies, institutes, and governmental laboratories interested in energy and coal research Universities sponsoring research programs on the Fischer-Tropsch Synthesis will also find this book useful

ISBN 0-12-058460-3, 1984, 320 pp , $55 00/£44 00

THE POLYSACCHARIDES
Volume 3
Edited by G O ASPINALL
A Volume in the MOLECULAR BIOLOGY Series

This third volume in the polysaccharide series completes the most comprehensive summary now available of polysaccharide chemistry and related aspects of biochemistry Authoritative coverage of major aspects of the subject is realized through individual chapters written by internationally recognized experts in their respective fields The principles behind current research on polysaccharides are thoroughly explained in this essential reference

ISBN 0-12-065603-5, 1985, 496 pp , $85 00/£85 00

THE ALKALOIDS
Chemistry and Pharmacology
Edited by ARNOLD BROSSI
VOLUME XXIV

Unlike other treatises which oversupply this field, *The Alkaloids* presents detailed up-to-date reviews on alkaloid chemistry as well as valuable information on the biochemical, pharmacological, and clinical properties of alkaloidal compounds

ISBN 0-12-469524-8, 1985, 384 pp , $85 00/£85 00

BIOSYNTHESIS AND BIODEGRADATION OF WOOD COMPONENTS
Edited by TAKAYOSHI HIGUCHI

The need to develop renewable alternatives to petroleum, coupled with the world's growing requirements for fuel and food, has focused renewed scientific attention on forestry and the wood sciences This volume analyzes the biosynthesis of biodegradation of wood, serving as a reference for those who seek to apply biotechnology to wood production and use

ISBN 0-12-347880-4, 1985, 704 pp , $99 00/£99 00

DRUG ANALYSIS BY GAS CHROMATOGRAPHY
DAVID B JACK

Following an introduction to the column, the most important part of the gas chromatograph, this book describes derivatization techniques (with examples using drugs), measurement of purity, stability, and the analysis of excipients and preservatives, determination of active ingredients, analysis of drugs and their metabolites in body fluids, and the use of gas chromatography to identify the "unknowns' found in drug screening Concluding the text, by way of an envoi, is a reproduction of the article, "Enlightenment" by G Machata Anyone who has worked in or managed a chromatography laboratory will empathize with this account

ISBN 0-12-378250-3, 1984, 240 pp , $49 50/£40 00

BIOCHEMICAL ACTIONS OF HORMONES
Volume XII
Edited by GERALD LITWACK

FROM THE PREFACE This volume stresses modern molecular biology as it pertains to hormone action as well as basic work with hormone receptors Consequently, it should appeal both to endocrinologists and to workers in the field of molecular biology

ISBN 0-12-452812-0, 1985, 560 pp , $89 00/£89 00

FLOW CYTOMETRY
Instrumentation and Data Analysis
Edited by MARVIN A. VAN DILLA, PHILLIP N DEAN, OLE D LAERUM, and MYRON R MELAMED

Flow Cytometry Instrumentation and Data Analysis offers the most comprehensive treatment available of flow cytometry and sorting This technique, by which cells and chromosomes can be sorted, continues to gain importance in biology and medicine

The volume takes a conceptual approach and the material is largely non-mathematical Where mathematics are used, the reader is supplied with clear explanations of the physical basis for the equations

40 Amicon

The three-day conference and exhibition take place in the Novotel, Hammersmith. Details of the exhibits on each stand are given in the exhibition catalogue.

● The Commonwealth Mycological Institute (CMI) is one of four institutes and ten bureaux of the Commonwealth Agricultural Bureaux. It offers a range of services to biotechnologists, as well as mycologists and specialists in related disciplines. A key area of the institute's activities lies in consultancies and contract research With some 300,000 reference specimens of microfungi (plus 11,000 in the culture collection), a substantial library, online database, and access to electron microscopes, computer and chemotaxonomic and biochemical facilities, the institute is well-placed to help solve problems involving microfungi. In addition, support from the Department of Trade and Industry to the culture collection and industrial services enables the institute to provide new and improved services to industry, and to build up biochemical data on strains held.
Reader Service No. 100.

● New Brunswick Scientific has developed a completely new series of pilot-scale fermentation systems designed for mammalian cell culture in bulk suspension and using microcarriers, and for bacterial cell culture. Of particular interest to users of pilot-scale fermenters are the design features in the standard open frame skid concept used by all NBS systems: all piping including filters, valves, regulators and steam traps is housed within the open frame skid, which makes installation and maintenance simple and trouble-free. At the laboratory scale, New Brunswick Scientific will be showing a new fermenter for shear-sensitive cultures, which uses a rotating lift tube for agitation, reducing shear forces on the culture to a minimum. A full range of monitoring and control instruments is available to complement both pilot and laboratory-scale fermentation systems. New Brunswick has recently acquired Biosearch, a company which manufactures a complete range of instruments and chemicals for the synthesis of oligonucleotides and peptides. Both the DNA and peptide synthesizers are fully automated, allowing researchers previously inexperienced in organic chemistry to successfully synthesize the most complex sequences. The instrument software ensures optimum conditions for each coupling once the sequence has been entered via the user-friendly keyboard.
Reader Service No. 101.

• The Bactometer, on the Bactomatic stand, is capable of handling 1–512 samples simultaneously, and performs total and selective counts in the range of 1 to 10 million organisms automatically, without the need for tedious procedures such as serial dilutions and plate counts. Results are typically available in 1–8 h. Based on impedance technology, the computer-assisted data system can display impedance growth curves which have been applied to optimization of a fermenter media phase sensitivity and culture metabolism studies, antibiotic/preservative/vitamin assays and sterility testing. Also on the Bactomatic stand is the Vitale AMS system for the rapid, automated identification of microorganisms. The computer-assisted system can identify between 1 and 240 organisms, typically within 4–10 h. The in-built database covers Gram-negative and Gram-positive bacteria, common pathogens and yeast, and can also determine MIC values and sensitivity for up to nine antimicrobial agents simultaneously.
Reader Service No. 102.

● Roth Scientific is marketing a series of versatile bench-top fermenters, engineered by Applikon of Holland. A feature of the systems is simplicity of use. Pilot-scale units are similarly available in volumes of 20l to 300 litres Applikon offers a choice of borosilicate glass fermenter vessels pilot vessels for bacterial culture have a ratio of height to diameter of 3:1 while those for animal/plant work are shorter and wider, with a 2:1 ratio. The range of vessels includes flat-bottomed, round-bottomed (supported in a tripod) and jacketed vessels all of which can be used to successfully grow bacteria, filamentous organisms, and plant and animal cells. Two forms of stirrer assembly can be specified — a mechanically driven lipseal assembly or a powerful magnetically coupled stirrer which remains coupled even at high speed or high viscosity Other products offered by Roth Scientific in the Biotechnology range are a versatile ultrasonic disintegrator, which is capable of processing four samples simultaneously, complete high-pressure liquid chromatography systems and a range of freezers and thermostatic baths.
Reader Service No. 103.

●Applied Biosystems has chosen the *Nature* exhibition for the launch of its new UK subsidary, Applied Biosystems Ltd. Among the facilities available are technical support and service laboratories, substantial stocks of reagents and solvents, and a specialist service for protein sequencing, peptide synthesis and DNA synthesis. At the exhibition, there will be on display three new products: the Model 120A PTH Analyser, a specially designed chromatography system for use either 'on-line' with the Model 470A gas-phase protein sequencer (also be on display) or as a 'stand-alone' system for the analysis of phenylthiohydantoin (PTH) amino acids All common PTH amino acids are resolved to better than 95%, with detection sensitivity of less than 1 picomole The fully automated Model 381A DNA synthesizer produces high-purity, defined-sequence oligonucleotides quickly and economically, with routine coupling yields of 98 – 100% and synthesis of oligonucleotides with over 100 bases The Model 380B DNA synthesizer has been developed as a successor to the 380A and has a new 'touch-screen' CRT control and built-in programming to allow the use of any synthesis strategy. Also on display will be the Model 430A solid-phase peptide synthesizer
Reader Service No. 104

● Bioengineering UK Ltd will be exhibiting a range of fermentation reactors which includes two new products: the paddle stirrer and visual safety reactor. The paddle stirrer is an agitation system which has particular application in the culivation of delicate cells. It can be used to convert a conventional stirred tank into a delicate cell reactor. The paddle stirrer system provides a novel solution to the problem of achieving a compromise between agitation effect and dissolved oxygen transfer, using an inversion of a rotational motion which simultaneously disperses and homogenizes. The stirrer transmits its energy mainly by impulse without shear and burbling. The visual safety reactor, or foil reactor, uses a foil cylinder of high mechanical strength in place of an equivalent glass cylinder. The advantage of the new reactor is that it eliminates the risk of accident when sterilizing glass vessels *in situ*. Visibility is better than with glass, and different foils can be experimented with to obtain novel configurations. The foil can be disposed of after use, thus eliminating the need for extensive cleaning. This concept also allows inexpensive development of 'tower'-type reactors and experimentation with air-lift systems.

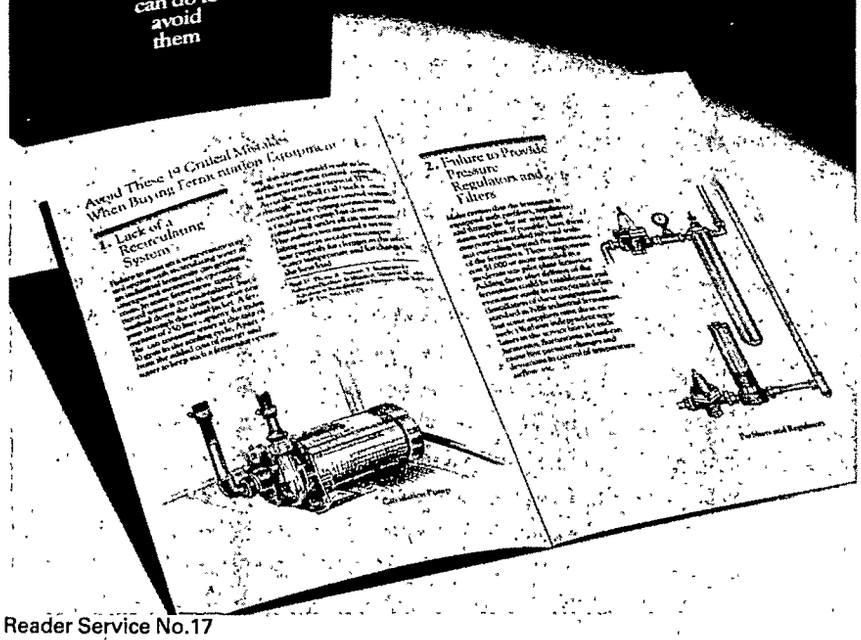
How to avoid the 19 critical mistakes in buying fermentation equipment

Make one mistake and you can have problems that include inadequate process control, permanent operator inconvenience and costly downtime.



Now NBS has published a comprehensive review of the problems and pitfalls that await the unwary buyer of industrial fermentors — and some very practical suggestions to help avoid them.

Called *19 Critical Mistakes Made in Buying Fermentation Equipment and What You Can Do to Avoid Them*, this practical guide is available without charge.

Send for your free copy today. New Brunswick Scientific Co., Inc., P.O. Box 986, Edison, NJ 08818. (201) 287-1200 or (800) 631-5417.

19 CRITICAL MISTAKES made in buying fermentation equipment and what you can do to avoid them

Reader Service No.17

● The Celltech stand features a range of immunoprocessing reagents based on monoclonal antibodies for the purification of α, γ and, most recently, β-interferon. Each kit provides single-step, high-yield purification. Celltech's range of monoclonal-based assays includes a gamma immunoradiometric assay (IRMA) for the assay of γ-interferon and NK2 and YOK IRMA for assay of different subtypes of α-interferon. *Abstracts in BioCommerce* (ABC), a commercial news index produced twice monthly by Celltech, is now available as an online computer database. At the Celltech stand the database will be demonstrated in action.
Reader Service No. 106.

● A new 2-litre airlift fermenter that will be ideal for monoclonal antibody production, media optimization and other similar applications is available from LH Fermentation. Based on a 2-litre total volume glass vessel, the fermenter has a working volume of 1,700ml with a removable glass draught tube and a stainless-steel top plate. This has ports for oxygen and carbon dioxide electrodes and other sensors. Temperature control is via thermostatically controlled water circulated around a jacket on the glass vessel; agitation is achieved on the standard unit by the 'airlift' principle with a glass sinter providing the gas dispersion. The LH Fermentation stand will also feature a new 30-litre airlift fermenter which is fitted with complete instrumentation and a gas blending system which can accommodate the culture of shear-sensitive animal and plant cells. And LH's new microprocessor-based fermentation control package can monitor eight parameters in single or multiple fermentation.
Reader Service No. 107.

●EBIP, the European Biotechnology Information Project, based at the British Library in London, and run with the help of European Commission funding, is investigating information provision in biotechnology across a broad front. It has produced a wide range of guides to information sources in key areas such as safety and regulations, business information and culture collections. EBIP is backed by the full resources of the British Library, and EBIP services are also available via the Online system DIMDI.

Plenum: The Nature of Science

AIDS-ASSOCIATED SYNDROMES
edited by Sudhir Gupta

Active investigators in AIDS research present the most recent data regarding the etiological agent—or agents—of AIDS, the immunological characteristics of some patients in the early stages of AIDS, various therapeutic modalities that are available for the treatment of AIDS, early AIDS (persistent generalized lymphadenopathy), and patients who demonstrate asymptomatic acquired deficiency Volume 187 in the series Advances in Experimental Medicine and Biology

0-306-42016-3/proceedings/176 pp + index ill /1985/$39 50 ($47 40 outside US & Canada)

PRINCIPLES OF MEDICAL THERAPY IN PREGNANCY
edited by Norbert Gleicher

Nearly 200 chapters by leading specialists cover virtually every problem physicians encounter in managing medical disorders during pregnancy The most comprehensive, in-depth reference text available on the subject, this book is essential reading for obstetricians, internists, and all clinicians who deal with patients in this special circumstance

0-306-41845-2/1,320 pp /ill /1985
$125 00 ($150 00 outside US & Canada)

BIOACTIVE POLYMERIC SYSTEMS
An Overview
edited by Charles G. Gebelein and Charles E. Carraher, Jr.

This new book reviews a wide variety of natural, pseudonatural, and synthetic polymeric systems Approaches and techniques are outlined for both medical and nonmedical applications, controlled release systems, and special experimental techniques

0-306-41855-X/690 pp /ill /1985
$95 00 ($114 00 outside US & Canada)

HYBRIDOMA TECHNOLOGY IN THE BIOSCIENCES AND MEDICINE
edited by Timothy A. Springer

State-of-the-art hybridoma technologies—including the uses of products secreted by T cell clones, immunization with synthetic peptides, and the use of antibodies in gene cloning—are described in this broad overview of the advances and developments in the field

text adoption price on orders of six or more copies $45 00

CHEMICALLY MEDIATED INTERACTIONS BETWEEN PLANTS AND OTHER ORGANISMS
edited by Gillian A. Cooper-Driver, Tony Swain, and Eric E. Conn

An authoritative study of the role of plant secondary compounds in a number of ecological interactions. Topics covered include plant detection of pathogens, the biochemical response of plants to fungal attack, interactions between plants and microorganisms in the soil, allelopathy and allelochemicals in plants, multichemical responses in plant–insect interactions, pheromonal communication between plants; and the deterrent effect of plant secondary compounds on herbivores Volume 19 in the series Recent Advances in Phytochemistry

0-306-42006-6/proceedings/256 pp /ill /1985

Review Editor:
C. R. Lowe, *University of Cambridge, The Biotechnology Center, Downingstreet, Cambridge CB2 3EF U.K.*

Aims and Scope

The journal provides a medium for the rapid publication of full-length articles as well as short communications on various aspects of biotechnology. Information on new or potential applications of biotechnological relevance in the following areas will be considered for publication:

- molecular biology
- genetics
- biochemical aspects of metabolism and its control, including viral, microbial, plant and animal cell systems
- process development and its control, including computer applications automation and the development of (bio)-sensors as applied to biosystems.

The overriding criteria for publication are originality, high scientific quality and interest to a multidisciplinary audience.

Reader Service No.41

The Heraeus B5060 cell culture incubator.

● A new, sophisticated cell culture incubator, the electronically-controlled Heraeus B5061 'Auto-Zero', will be displayed on the Heraeus Equipment stand. The CO_2 control on the B5061 has an automatic self-adjusting measuring system to keep the operating parameters constant and reproducible, making manual recalibration of the CO_2 zero unnecessary. This is particularly helpful when the incubator is used for long-term cultivation and manufacturing. Additionally, in the O_2 version, the O_2 zero can be calibrated without interrupting the operation of the incubator. Also on show will be the Heraeus B5060 incubator which, like the B5061, is available with linings made in a choice of bactericidal and fungicidal copper, or stainless steel. With the CO_2 version of the B5060 the temperature and CO_2 content are adjustable with great accuracy, so that the optimum conditions for cell and tissue culture can be created. It has an electronic temperature controller and an adjustable temperature limit controller with a recording facility. An easily drained water bath provides constantly high humidity.
Reader Service No. 110.

● Laboratory and Electronic Engineering Co (LEEC) will be featuring their automatic CO_2 incubators. The GA3 is the large slimline version of the popular 150-litre model GA2, featuring a single chamber with double doors, and a capacity of 330 litres. Both incubators are designed for techniques of open dish tissue cell culture in which the *p*H of the medium is maintained in equilibrium with the incubator's CO_2 atmosphere. The incubator automatically controls the CO_2 concentration to a pre-set level, and a percentage CO_2 meter on the control panel monitors the output of a thermal conductivity detector cell which continuously analyses a gas sample from the chamber. LEEC are now offering a sterilization feature as an optional extra on both models. An additional boost heating element raises the chamber air temperature to a pre-set temperature of 90–100°C. Also on display will be a selection of compact incubators, tissue culture roller apparatus and drying cabinets.
Reader Service No. 111.

● Flow Laboratories Ltd will be exhibiting a selection of new and existing products for the following: laminar air flow and filtration, microplate technology and tissue culture and diagnostics. On display will be the complete new range of disposable membrane filters, including minifilters for use with syringes, and single or double capsules for the filtration of larger volumes of liquid; and new models of the Titertek enzyme immunoassay readers the Multiskan MCC/MCC340, a twin reader, with the capacity to read, shake and incubate two plates simultaneously; HTE Multiskan Plus with a barcoded microplate identification system; and Fluoroskan for fluorimetric enzyme immunoassays. All these microplate readers have a bidirectional computer control facility which enables them to be used for kinetic studies. There is also a new range of viral diagnostic reagents for use in complement fixation, enzyme munoassay and immunofluorescence techniques. Other products on show include a range of liquid-handling devices such as Titertek digital multichannel pipettes and a selection of disposable plastics, tissue culture media and glassware.
Reader Service No. 112.

● Becton Dickinson will exhibit the Falcon range of disposable tissue culture plastics and related products. All Falcon Labware products, from the smallest Petri dish to the largest roller bottle, are sterilized by gamma irradiation. Products featured will include Primaria, a surface-odified plastic substrate for primary cell culture, and the FAST system for simultaneous screening via ELISA of all 96 wells of a hybridoma culture plate for clones producing antibodies of desired specificity, together with disposable filter units, pipettes, multi-well plates and tubes.
Reader Service No. 113.

● The Cetus Pro/Pette, an instrument for the rapid and accurate processing of microtitre plates, will be the centre of Anachem's display. The machine was developed for general cell culture, hybridoma studies and ELISA applications. Plates can be processed either in rows or columns with tip change between rack movement if required. Single wells may be accessed, allowing transfer of samples from tubes to individual wells. The Pro/Pette can also empty and refill wells for serial dilutions or transfer between plates, again with optional tip change. From Gilson, there will be on display pipettes, dispensers, diluters and automatic liquid handlers with 'robotic arms'. Analytical and preparative HPLC equipment, together with examples of Anachem's range of columns and accessories, will also be shown.
Reader Service No. 114.

These notes are based on information provided by the manufacturers. To obtain further details about these products use the reader service card bound inside the journal.

ACADE DIAGNOSTIC SYSTEMS S.A./N.V., a company specialising in non-isotopic immunoassay using particle counting, is looking for research groups with access to good quality antisera directed towards clinically important assays who would be free to enter into a development contract and/or provide such antisera in commercial quantities.
If interested, please write with full details to Managing Director, ACADE DIAGNOSTIC SYSTEMS S.A./N.V., Passage de la Vecquée, Box 4100, 1200 Brussels, Belgium. Telephone: 02/762.89.75. Telex: 65867. Replies may be in English, German, French or Dutch.

Reader Service No.69

LASERS SPECIAL ISSUE

The 25 July issue of *Nature* will feature specially commissioned articles on lasers and laser applications, including V. Letkhov on lasers in biology and medicine, S. D. Smith on optical computers, M. Key on X-ray lasers and the late A. Kaster on the early history of the laser.

The issue will also contain a Product Review section on lasers and related products. Manufacturers are invited to send press releases on products or on novel applications to the address below, to arrive not later than 4 July.

Nature (Product Review),
4 Little Essex Street,
London WC2R 3LF, UK.

June meeting

28-29 June, **Investigation and Belief — 3rd Annual International Conference on the Paranormal,** University College, London, UK (M. Hutchinson, Secretary, CSICOP, UK Branch, 10 Crescent View, Loughton, Essex IG10 4PZ, UK)

July meetings

8-12 July 1985, **7th International Meeting on NMR Spectroscopy,** Cambridge, UK (Dr J. Gibson, The Royal Society of Chemistry, Burlington House, London W1V 0BN)

September meetings

1–4 September 1985, **First International Symposium on ESR Dating**, Ube, Japan (Prof. Ikeya, Secretary of the Symposium, Technical College, Yamaguchi University, Tokiwadai, Ube 755, Japan)

2–3 September 1985, **International Symposium on Impact Testing and Performance of Polymeric Materials**, Guildford, UK (Miss Rachael Alexander, Short Courses and Conferences Section, Bureau of Industrial and External Liaison, University of Surrey, Guildford, Surrey GU2 5XH)

3–6 September 1985, **Second International Symposium on the Synthesis and Applications of Isotropically Labelled Compounds,** Missouri, USA (Dr R. Wilk, Symposium Coordinator, School of Pharmacy, 5100 Rockhill Road, Kansas City, MO 64110 USA)

16–19 September 1985, **International Environment and Safety Conference**, Olympia, London, UK (D. Parker, Conference Coordinator, International Environment and Safety, Labmate Limited, Newgate, Sandpit Lane, St Albans, Herts. AL4 0BS, UK)

October meetings

7–9 October 1985, **International Symposium on Biotechnology in the Food Processing Industry**, Minnesota, USA (Lynette Marten, University of Minnesota, St Paul, Minnesota 55108 USA)

7–10 October 1985, **Electronic Imaging '85 – International Electronic Imaging Exposition and Conference**, Massachusetts, USA (R. Murray, Institute for Graphic Communication, 375 Commonwealth Avenue, Boston, MA 02115, USA)

8–10 October 1985, **International Conference on the Occupational and Environmental Significance of Chemical Carcinogens**, Bologna, Italy (Organising Committee, International Conference on Chemical Carcinogenesis, c/o Istituto di Oncologia, Viale Ercolani, 4/2, 40138 Bologna, Italy)

Please send 'Announcements' entries to: The Editor, Nature, 4, Little Essex Street, London WC2R 3LF, UK

20–23 October 1985, **Halifax '85–16th Annual Underwater Mining Institute**, Nova Scotia, Canada (H. Joseph, Ocean Mining Division, 355 River Road, Ottawa, Ontario, K1A 0E4)

November meetings

7-9 November 1985, **International Congress on Neo-Adjuvant Chemotherapy**, Paris, France (SOMPS-1st International Congress on Neo-Adjuvant Chemotherapy, Pavillion Jacquart, Hôpital de la Salpétrière, 47 Boulevard de L'Hôpital 75651 Paris, France).

19-21 November 1985, **International Conference on Advanced Welding Systems,** London, (The Conference Office, The Welding Institute, Abington Hall, Abington, Cambridge CB1 6AL, UK).

20-22 November 1985, **International Conference on Nitrates in Water**, Paris, France (G. Martin, Ecole Normale Supérieure de Chimie, 35000 Rennes-Beaulieu, France).

December meetings

2-4 December 1985, **International Conference on Spacecraft Structures,** Toulouse, France (CNES, Department des Affaires Universitaires 18, avenue Edouard-Belin 31055 Toulouse, France)

3–5 December 1985, **Ninth International Online Information Meeting**, London, UK (J. Mulligan, Learned Information (Europe) Ltd, Besselsleigh Road, Abingdon, Oxford OX13 6LG)

3-6 December 1985, **Fourth International Meeting on Biostereometrics '85,** Cannes, France (J. Prado, Coordinator Central du Congres, ANRT-Association Nationale de la Recherche Technique, 101, Avenue Raymond Poincaré, 75116 Paris, France)

4-5 December 1985, **International Conference on Electric and Magnetic Fields in Medicine and Biology,** London, UK (C. Dagnall, IEE Press Office, Savoy Place, London WC2R 0BL, UK).

11-13 December 1985, **IFAC Symposium on Modelling and Control of Biotechnological Processes,** Noordwijerhout, The Netherlands (IFAC/BIC '85 c/o Klvl, PO Box 30424, 2500 GK The Hague, The Netherlands).

Appointments

Dr Geoffrey Rivett has been appointed Senior Medical Officer at the Department of Health and Social Security. He will take charge of Med PCR division (Primary Care, Regional Medical Services) with effect from 1 July 1985.

The Council of the Royal Society has appointed **Dr P.T. Warren** as Executive Secretary of the society,on the retirement of **Dr R.W. Keay.**

Dr Lewis Roberts, Director of the UK Atomic Energy Authority's Energy Research Establishment at Harwell, has been appointed the first professor of Risk Assessment at the University of East Anglia, Norwich.

Two appointments have been made to the Medical Research Council with effect from 1 August 1985. **Professor Wing** will be Chairman of the MRC's Neurosciences Board, and **Professor Newsom-Davis,** the present Chairman of the Neurosciences Board, will be an independent scientific member.

Three new members have recently been appointed to the Engineering Council. They are **Mr Norman Holland**, UK Group Standards Manager of Philips Electronic and Associated Industries, **Sir Richard 'Brien**, Chairman of the Engineering Industry Training Board, and **Sir Robert Telford**, Life President of The Marconi Company Ltd.

Loughborough University of Technology has appointed **Professor John Phillips** as Vice-Chancellor from 1 January 1986, in succession to Sir Clifford Butler. Professor Phillips is at present director of research and Wolfson Professor in the Wolfson Institute at the University of Hull.

Awards

PROFESSOR Gert Utermann from the Institute for Medical Biology and Genetics of the University of Innsbruck has been awarded the Morgagni Medal for his investigations on the pathophysiology of familial hyperlipidaemias. The G.B. Morgagni Young Investigator Awards will be awarded to Dr G. Bolli of the University of Perugia and Dr E.Van Obberghen of the University of Nice.

The William Hopkins Prize of the Cambridge Philosophical Society has been awarded to Dr D.O. Gough of Churchill College for his pioneering achievements in the subject of helioseismology.

The University of Glasgow has appointed **Dr David W.T. Crompton** to the John Graham Kerr Chair of Zoology with effect from 1 October 1985. He is presently lecturer in parasitology in the University of Cambridge, fellow of Sidney Sussex College, Cambridge and adjunct professor in the division of nutritional sciences, Cornell University, New York.

The International Association of Gerontology has awarded the 1985 Sandoz Prize jointly to Sir Martin Roth, Professor of Psychiatry at Cambridge (UK), and Dr Karl Esser, Professor of Botany at the University of the Ruhr (FRG).

The Jung Foundation for Science and Research 1985 prize for Medicine has been awarded to three recipients. The prizewinners are: **Professor Hendrik Coenraad Hemker** — for work on the biochemistry of blood anticoagulation, **Professor Rudolph Pilchmayer** — for work on liver transplantation and **Professor Peter K. Vogt** — for work on the genetic analysis of retroviruses.

UNIVERSITY OF LONDON
THE LONDON HOSPITAL MEDICAL COLLEGE

MLSO

IN THE DEPARTMENT OF FORENSIC MEDICINE

A state registered MLSO is required to take charge of the Histopathology section. The postholder must have a wide knowledge of Histopathological techniques, including diatomaceous preparation with preparation of gross specimens as required for Court presentation. In addition the postholder will be responsible for the administration of toxicological samples and the conveying of same to Guy's Hospital for their analysis. Whitley salary scale £5,738 — £8,096 plus £1,084 London Weighting

Contact the Assistant Secretary (Personnel) LHMC Turner Street, London E1 2AD (01-377-8800 x 3/12) for an application form which should be returned within 21 days of this advertisement. (6840)A

THE UNITED MEDICAL AND DENTAL SCHOOLS

St Thomas's Campus

RESEARCH ASSISTANT
(possibly post-doctoral)

required to work on immunity to and the molecular biology of rubella virus. Virology experience essential; some knowledge of ELISA and PAGE techniques and use of monolonal antibodies an advantage.

Funding for post is currently being sought; anticipated start date early September.

Salary according to age and experience.

Applications with cv and names and addresses of two referees to Staffing Officer, Dean's Office, St Thomas's Hospital Medical School, London SE1 7EH, not later than 18th July, 1985 quoting ref: STH/V/38. (6859)A

IMPERIAL CANCER RESEARCH FUND
Developmental Biology Unit
Oxford

RESEARCH SCIENTIST

Applications are invited for a five year appointment with the prospect of tenure. Applicants should be specialists in any area of developmental biology, of senior postdoctoral status and able to plan and execute an independent research programme

The Unit which will open early in 1986 is situated in the Zoology Department of Oxford University The Director is Prof R Gardner and permanent staff members are Drs D Ish-Horowicz and J Slack

Salary range £11,675 to £14,925 (revision pending).

For further details write or telephone Ms S M Hurley, Imperial Cancer Research Fund, 44 Lincoln's Inn Fields, London WC2A 3PX on 01-242 0200 ext 305 Please quote reference 82/85 (6819)A

UNIVERSITY OF CAMBRIDGE

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANT

required to work with Dr D S Bendall on an SERC-funded project to isolate and characterize ferredoxin-plastoquinone oxidoreductase, the key enzyme of cyclic photophosphorylation in chloroplasts The post will be available for three years from 1st October 1985 with salary in the range £7,980 — £8,920 (under review) according to age and experience

Applications (with curriculum vitae and names of two referees) should be sent to Dr D S Bendall, Department of Biochemistry, University of Cambridge, Tennis Court Road, Cambridge, CB2 1QW, before 19th July 1985. Further details from Dr Bendall, Tel: 0223-351781. (6834)A

New Technologies Manager

Clinical Reagents
c. £24,000 + car

My client is a leading international company providing specialised products for use in health care, life-sciences research and industry. Its firmly established Clinical Reagents Department, is embarking on a major expansion programme.

We are searching for a key manager for the department – a person combining research credibility with entrepreneurial flair. The New Technologies Manager will be expected to operate at the leading edge of the department, foraging inside and outside the company for new technologies that can be applied in clinical reagents development. This will obviously need an acute awareness of the state-of-the-art together with business acumen. The strength to 'product champion' an idea through to manufacture will be a key role.

The management responsibilities associated with this job are for some 40 professionally qualified scientists and 3 section leaders who operate from 'well-found' laboratories (new technology, instrumentation and clinical microbiology).

We would like to discuss this pioneering appointment with candidates aged between 30-40 who have several years' experience of clinical diagnostics, ideally including a knowledge of instrumentation. Recent experience will ideally have been with a diagnostic or a biotechnology company where the expertise could be applied to clinical diagnostics. High academic attainment is a pre-requisite.

If you feel you have the ability called for in this advertisement, we would like to take things further with you. In the first instance send your curriculum vitae in confidence, quoting reference NTM/BT, to Geoffrey King, Managing Director at the address below

This appointment is open to both men and women.

Cambridge Recruitment Consultants
International Biotechnology Division
1a Rose Crescent, Cambridge CB2 3LL Telephone 0223 311316

CANADA

IDRC/CRDI

The International Development Research Centre (IDRC) is a corporation funded by the Government and created by the Parliament of Canada to support research designed to adapt science and technology to the needs of developing countries.

For its Regional Office in Eastern and Southern Africa, situated in Nairobi, Kenya, the Centre is seeking a

Regional Representative for the Health Sciences Division

The representative will be required to identify research and research institutions in the health sector in Eastern and Southern Africa; assess research needs and capabilities, as well as constraints to the conduct of research in the region; work with researchers in developing research proposals, and monitor on-going projects.

Qualifications and Experience Required

- **Medical degree plus graduate training in Public Health or Tropical Medicine, *or* Doctoral degree in Public Health, Epidemiology or equivalent discipline.**
- **Ten years' experience in research and research administration;**
- **working experience in developing countries;**
- **knowledge of and contacts with governmental, university and private organizations in the health field in Eastern and Southern Africa;**
- **proven independent research capability in the health field;**
- **Excellent command of both spoken and written English and working knowledge of French.**

Working Conditions: Extensive travel required.

The successful candidate will be eligible for a generous overseas benefit and allowance package.

Interested candidates should send their résumé to: Competition BR/NTR, Human Resources Division, IDRC, P.O. Box 8500, Ottawa, Ontario K1G 3H9, before August 15, 1985. (NW1867)A

MEDICAL RESEARCH COUNCIL

NATIONAL INSTITUTE FOR MEDICAL RESEARCH

Scientific Appointment in the Laboratory of Gene Structure and Expression

(Revised advertisement)

Applications are invited for a scientific position in the Laboratory of Gene Structure and Expression (Head: Dr F. G. Grosveld) in the field of studies on the regulation of gene expression. The candidate will be expected to carry out independent research in an area which is compatible with the programme of the Laboratory and should have relevant postdoctoral experience. Extensive experience with recombinant DNA technology and tissue culture techniques is definitely required.

Information about current activities in the laboratory and elsewhere in the Institute is available in the Institute's Annual Report which has been distributed to major Medical Libraries and can be obtained by post from the Director's secretary.

The position might be filled either by a career or a short-term appointment, according to the age and experience of the candidate. The salary will be at an appropriate point on the Council's range equivalent to University non-clinical academic staff scales, plus £1,233 London allowance and superannuation provision.

Applications should include curriculum vitae, list of publications, a brief statement of research plans (about 1000 words), and the names of three persons to whom reference may be made, and sent to the Director, National Institute for Medical Research, Mill Hill, NW7 1AA by 19th July 1985, quoting ref: GSE/11/C. (6854)A

NEUROENDOCRINOLOGIST

Department of Physiology

QUEEN'S UNIVERSITY

A vacancy exists for an experienced neuroendocrinologist. The preferred applicant should have the Ph.D and/or the M.D. degree, several years teaching experience and a record of independent research of high quality. The applicant will be expected to lead an active research program and to participate in undergraduate and graduate teaching. The facilities for research are outstanding and the appointment is a regular one under tenure regulations. The appointment will be made at a level appropriate to the candidate's qualifications

Applications are encouraged from candidates of either sex. Applicants should submit a curriculum vitae, a brief statement of their research interests and objectives, selected reprints, and the names of three referees from whom a confidential assessment of research and teaching abilities may be obtained to: Dr. V. C. Abrahams, Department of Physiology, Queen's University, Kingston, Ontario, Canada K7L 3N6. (Second Advertisement). (NW1870)A

DIRECTOR

BLOOMFIELD CENTRE FOR RESEARCH IN AGING

AT THE LADY DAVIS INSTITUTE FOR MEDICAL RESEARCH

In Association With

MCGILL UNIVERSITY

The Lady Davis Institute will establish a new research group for studies in aging. Initially the group will consist of the leader and two junior investigators, with the focus of interest on various aspects of the biology of the aging process. It is anticipated that three more positions will become available for work in the psychosocial and epidemiological aspects of aging.

The successful candidate (M.D. or Ph.D.) must have a demonstrated research record of aging or a closely allied area. A tenure-track university appointment will be made at the level of Associate Professor or Professor. **Please submit a current curriculum vitae, a short description of personal research interests, a brief comment on the desired areas of expertise of the two junior investigators to be recruited, and the names of three referees by August 1, 1985, to: Dr. Norman Kalant, Director, Lady Davis Institute for Medical Research, 3755 Cote St. Catherine Road, Montreal, Que. Canada H3T 1E2.**

In accordance with Canadian immigration regulations applications from Canadian citizens and landed immigrants will be considered first. (NW1873)A

ETH ZÜRICH

Applications are invited for a faculty position in

Geology

at the Department of Earth Sciences of the University and the Swiss Federal Institute of Technology in Zurich.

The new professor will be expected to participate in the general and historical geology parts of the basic geology course, to teach historical and regional geology in advanced courses and to supervise diploma and doctorate level students in field work projects.

In research a particular interest in stratigraphy with interaction in sedimentology and tectonics is desired. Candidates should be willing and able to teach at all university levels and to cooperate with colleagues within and outside the department.

Applications with curriculum vitae and list of publications should be submitted before July 15, 1985, to:
The President of the ETH Zurich
Prof. H. Urspring
CH-8092 Zurich. (W1952)A

Associate Director Drug Delivery Research

Smith Kline & French Laboratories is establishing a multi-disciplinary research team of Ph.D. scientists to investigate fundamental approaches to the delivery of drugs. We are currently seeking an individual to lead the Physiochemistry Section and serve as an Associate Director in the Drug Delivery Department. Research activities emanating from this Section should provide a mechanistic understanding of solute transport to membrane surfaces and through biological membranes leading to development of strategies to control the luminal flux of drugs.

Specific areas of research may include: (a) mass transport of drugs across selected biological membranes, (b) characterization of those membranes and associated luminal contents with respect to biochemical activity and physiological factors, (c) carrying out mass transport studies using pharmacokinetic principles to define potential routes of administration, (d) developing carrier-based systems for targeting and/or protecting macromolecular drugs, and (e) defining interactions of polymeric-based delivery systems and/or carriers at biomembranes. Initial emphasis is to be placed on delivery of peptides and proteins.

The candidate should be a nationally or internationally recognized scholar with an established record of significant scientific achievement in areas impacting on drug delivery.

Presently located in Philadelphia, the Department will be relocating to a new state-of-the-art Research and Development facility near Valley Forge. We offer an excellent salary, benefits and relocation package as well as the opportunity for personal and professional growth. Please forward your resume to George P. Kissell, Jr., Manager of Personnel Relations, Smith Kline & French Laboratories, 1576 Spring Garden St., Philadelphia, PA 19101. (NW1884)A

SK&F
A SmithKline Beckman Company

RU leiden

UNIVERSITY OF LEIDEN

The Center for Bio-Pharmaceutical Sciences has a vacancy for a

full professor of biopharmaceutics (m/f)

IN PARTICULAR DRUG TARGETING

vacancy number: 5-162/2407

The Division of Biopharmaceutics of the Center is intended to conduct research on modern methods of drugs targeting **in vivo,** such as,
- coupling of drugs to macromolecular or colloidal systems, incorporating target tissue selective substrates (e.g. antibodies);
- selective bio-activation **in situ** using prodrugs and enzyme systems specific to target tissues.

The Professor of Biopharmaceutics will play a major rol in building up the Division's research and teaching.

The Center for Bio-Pharmaceutical Sciences is a new part of the Faculty of Mathematics and Natural Sciences. Its primary objective is to conduct multidisciplinary research into the production of drugs, and their disposition and effects in man and animals. In close relation to its research, the Center will also offer a 3 year undergraduate program (M.Sc.level) as well as a 4 year graduate program (Ph.D.level).
In addition to the Division of Biopharmaceutics, the Center contains Divisions of Analytical Chemistry, Pharmaceutical Technology, Pharmacognosy/Plant Cell Biotechnology, Pharmacology, Medicinal Chemistry and Toxicology.
All Divisions have 1 full professorial chair, 2 senior faculty positions, 4 positions for graduate research assistants, and 2,5 supportive functions (2.0 technical and 0.5 administrative). All positions in the Division of Biopharmaceutics are still vacant.
The profile of the Center has been specified in a brochure which may be obtained from the Secretary Advisory Committee (address below).

Candidates should have a vast experience relevant to the research objectives of the Division of Biopharmaceutics. They are expected to be able to stimulate research collaboration with other Divisions of the Center as well as with outside partners, including industry. Proficiency in management of multidisciplinary research is an asset. In addition, candidates should be prepared to engage in the design and teaching of undergraduate and graduate courses.

Candidates should also be willing to learn Dutch.

Candidates are invited to send a written application, with full C.V., to the Secretary of the Selection Advisory Committee, Mr O. H. Postma, P.O. Box 9502, 2300 RA Leiden, The Netherlands (phone 071-148333, ext. 4219 or 4788), within two months after the publication of this advertisement. Further information may be obtained at the same address from the Committee Chairman, Prof. dr H. E. Jungınger (phone 071-148333, ext. 3856 or 3850).

UNIVERSITY OF FLORIDA
FLORIDA STATE MUSEUM

DIRECTOR

Applications are invited for the Directorship of one of the largest and most active university museums of natural history The FSM emphasizes research and exhibits on the natural and cultural history of Florida and Latin America

The FSM faculty consists of 24 salaried curators who also hold titular appointments in related teaching departments. Physically the Museum is a modern structure central to the campus with one floor for each of its three departments, Natural Sciences, Anthropology, and Interpretations The Museum serves dual functions as the Florida State Museum, with permanent and travelling exhibits and a statewide membership program, and as a University Museum, with strong research and educational missions.

The Directorship is equivalent to the rank of Dean within the University of Florida Applicants should have appropriate experience and vision to plan the Museum's long-range growth, to develop a statewide constituency and fund-raising campaign, to supervise the research and public education programs of the Museum; and to maintain liaison with officers and lawmakers in state government.

The position opens as of January, 1986 The salary is commensurate with qualifications and experience and competitive with that of other major museums Applications naming three references should be postmarked no later than October 31, 1985 to.

Dr. David Webb
Florida State Museum
Gainesville
FL 32611
USA

The search will be conducted under Florida's "Government in the Sunshine" Law The University of Florida is an Equal Employment Affirmative Action Employer.

PROFESSOR AND CHAIRMAN

Department of Medical Microbiology and Infectious Diseases

The Faculty of Medicine, University of Alberta, invites applications for the position of Professor and Chairman, Department of Medical Micro biology and Infectious Diseases, the appointment to be effective July 1, 1986. The successful candidate will be expected to provide administra tive direction and leadership direction and leadership to an actively dev eloping department. In order to enhance undergraduate and graduate teaching as well as research, the current staff of 8 faculty members in Medical Microbiology is being increased by cross appointments of 10 faculty members in Infectious Diseases Medicine and Paediatrics. Current research interests are directed towards microbial pathogenesis. The activities of the University of Alberta Hospitals Microbiology Division are also integrated into the department.

Applicants should have an active research program and be able to attract extra-mural support. The programs of the Alberta Heritage Foundation for Medical Research provide an ideal opportunity to develop innovated research areas. The appointment will be at the professorial rank with salary communsurate with qualifications and experience. Applicants should apply enclosing a Curriculum Vitae and the names of three refer ees by August 31, 1985 to:

Dr Douglas R. Wilson
Dean, Faculty of Medicine
2J2 Walter Mackenzie Health
Sciences Centre
University of Alberta
Edmonton, Alberta T6G 2R7

The University of Alberta is an equal opportunity employer, but in accordance with Canadian immigration requirements, priority will be given to Canadian citizens and permanent residents of Canada. (NW1893)A

The European Molecular Biology Laboratory, an international research organization situated in Heidelberg, West Germany, invites applicants for the following vacancy at the Laboratory's Outstation at the «Institut Laue Langevin» site in Grenoble, France

BIOPHYSICIST

The successful candidate will have the responsibility of an instrument of light scattering (photocorrelation and Brillouin scattering) This instrument is part of the set-up of the Outstation which is doing structural molecular biology using neutron diffraction, X-rays, EM and light scattering The job will include a service activity helping visitors It is also expected that the scientist will by involved in one of the existing programmes

The candidate should have a good background in physical chemistry

An above-average salary will be offered to the successful candidate Certain allowances are payable in addition, such as family allowance, children's allowance and non-resident allowance, depending on personal circumstances

An initial contract of 3 years' duration will be offered to the successful candidate This contract may be renewed, depending on circumstances at the time of review.

HOUGHTON POULTRY RESEARCH STATION

Grant-Aided by the Agricultural & Food Research Council

IMMUNOLOGIST

Applications are invited from immunologists to join a group studying cellular interactions in the immune system of chickens with the long term objective of providing a rational basis for the development and presentation of vaccines, particularly novel vaccines produced by genetic engineering techniques The initial objective is the production and application of monoclonal antibodies specific for lymphocyte populations and subpopulations and the development of in vitro assays for soluble mediators such as interleukins

Applicants should have a first or upper second class honours degree in a biological subject and preferably a PhD, with at least two years relevant post-graduate experience.

The appointments will be made in the Higher Scientific Officer grade, salary: £7,435 × 6 to £10.039.

The position is available for a period of three years, commencing on a date to be arranged prior to October 2nd, 1985.

For further details and application forms please contact the Secretary, John Andrews at Houghton Poultry Research Station, Houghton, Huntingdon, Cambs, PE17 2DA, tel St Ives (0480) 64101. Closing date for applications is 12th July 1985.

The Houghton Poultry Research Station is an Equal Opportunities Employer (6802)A

KINGSTON POLYTECHNIC
School of Geology

SENIOR TECHNICIAN
Scale 4/5 £7,212 — £8,919
including London Allowance

A Senior Technician is required in the School of Geology to provide support in Mineralogy and Petrology, and structural Geology

Applicants should hold HND/C or degree in Geology or other related subject Preference will be given to those with suitable experience.

TECHNICIAN (Part-time)
Scale 2 £4,421.25 — £4,819.50
including London Allowance

The technician is required to work 27 hours a week to assist with support in Mineralogy and Petrology, and Stuctural Geology. Applicants should possess HND/C or degree in Geology or related subject. School leavers with relevant O/A levels will also be considered. Experience would be an advantage but is not essential

Application forms and further details from Staffing Officer, Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. Tel 01-549 1366 ext 205 Closing date 5th July 1985 (6831)A

KING'S COLLEGE LONDON (KQC) (QUEEN ELIZABETH CAMPUS AT KENSINGTON)
LECTURESHIP IN MOLECULAR GENETICS

Applications are invited for the above Lectureship in the Biochemistry Department, tenable from 1 October 1985, or as soon as possible thereafter.

The appointee will be responsible for teaching aspects of Molecular Biology to undergraduates and MSc students and will be associated with the MRC Human Genetic Diseases Group under the direction of Professor D Robinson.

A research interest in the application of molecular genetics to the diagnosis, treatment or elucidation of human disease states is therefore desirable.

Salary will be within the range £7,520 — £14,925 per annum plus £1,233 per annum London Allowance. Universities' Superannuation Scheme contributions are payable.

Preliminary informal enquiries should be addressed to Professor D Robinson at the Biochemistry Department, Queen Elizabeth Campus at Kensington, Campden Hill Road, London W8 7AH

Application forms and written further particulars can be obtained from Mr S P Harrow, Assistant Registrar, King's College London, Strand, London WC2R 2LS (tel 01-836 5454 Ext 2689). Applications should be submitted, with the names of not fewer than two referees, not later than 22 July 1985. (6881)A

UNIVERSITY OF EDINBURGH
DEPARTMENT OF FORESTRY AND NATURAL RESOURCES

POSTGRADUATE RESEARCH ASSOCIATE

Applications are invited for the post of NERC funded Research Associate to study genetic variation in a Forest Pathogen. The work will involve the measurement of variation in morphology, isozymes, and tolerance to monoterpenes in the ascomycete fungus Crumenulopsis sororia, a pathogen of pines

The appointment is for a three year period from 1st September, 1985 on the 1B salary scale.

Applicants should hold, or expect to obtain a first or upper second class degree in an appropriate biological science

Applications, including a curriculum vitae and the names of two referees, should be sent as soon as possible to Dr R A Ennos, Department of Forestry and Natural Resources, University of Edinburgh, King's Buildings, Mayfield Road, Edinburgh, EH9 3JU

THE UNIVERSITY OF NEW SOUTH WALES
Sydney, Australia
PROFESSOR
SCHOOL OF CHEMICAL ENGINEERING AND INDUSTRIAL CHEMISTRY
(Centre for Petroleum Engineering Studies)

The University of New South Wales has been designated by the Federal Government as the Centre for teaching and research in petroleum engineering in Australia. It is now in the process of establishing a National School of Petroleum Engineering that will serve the needs of the Australian Petroleum Industry. The University has established a Centre for Petroleum Engineering Studies which will offer undergraduate and postgraduate degrees in petroleum engineering commencing in 1986.

The Centre draws on existing expertise within the Schools of Chemical Engineering and Industrial Chemistry, Applied Geology and Mining Engineering in the Faculty of Applied Science. Applications are invited for appointment to a Chair. The successful applicant initially will be Director of this Centre, develop the undergraduate teaching program, contribute to research activity and extend existing links with industry.

Candidates should have a commitment to excellence in undergraduate and graduate education and have demonstrated research capacity and leadership in drilling, reservoir, production, or other areas of petroleum engineering. Industrial experience in oil and gas production is highly desirable.

Enquiries regarding the Chair may be addressed to the Dean of the Faculty of Applied Science or to Professor C J D Fell, Head of the School of Chemical Engineering and Industrial Chemistry, University of New South Wales, PO Box 1, Kensington, NSW 2033, Australia.

Salary. A$54,948

Subject to consent by the University professors may undertake a limited amount of higher consultative work.

The University reserves the right to fill any by invitation.

Applications close 16 August 1985.

For full information about conditions of appointment and method of application write to the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Equality of employment opportunity is University policy.

(W1957)A

TECHNICIAN or EMBRYOLOGIST with experience in mammalian embryology, required to work for IVF clinic in Athens. Salary negotiable. Interested persons should write in confidence to Dr H G Massauras, 3 Marasli Street, Athens 106-76, Greece. (W1920)A

ONCOGENE SCIENCE INC.

Expanding staff at Long Island, NY research facilities due to advances in

Oncogene and growth factor research

to develop products for the early

detection -- monitoring -- treatment of human cancers.

— Positions Available —

DIRECTOR OF BIOCHEMISTRY

Responsible to direct and coordinate corporate biochemistry program. Ph D in Protein Chemistry — purification and sequencing, 8-10 years postdoctoral experience. Strong publication record highly desirable. Will contribute to development of diagnostic and pharmaceutical products.

PROJECT DIRECTOR

Responsible for formatting diagnostic tests for HTLV-III infection and oncogene activation. Test development, pilot and scale-up operations, standardization of appropriate QC procedures. Ph D. in Immunochemistry. 5-7 years postdoctoral experience in immunoassay, format design, product development.

MOLECULAR BIOLOGIST

To participate in projects aimed at determining the role of oncogenes in human cancer using cDNA cloning, in situ hybridization and bacterial expression of antigens. Ph D in Molecular Biology, although candidates with Masters degree and appropriate experience will be considered.

Be part of the excitement at OSI.

Send resume and personal data to Scientific Director, Oncogene Science Inc., 222 Station Plaza North, Suite 330, Mineola, NY 11501

Competitive salary. Liberal benefits. Equity potential.

Equal Opportunity Employer (NW1885)A

UNIVERSITY OF WESTERN ONTARIO
LONDON, ONTARIO
CANADA
POST-DOCTORAL POSITION FOR BIOCHEMIST

with experience in enzymology (phosphorylation preferred) or in cloning and sequencing DNA for studies on developing lung. Position funded by Canadian MRC. Minimum stipend approximately $20,000.

Send curriculum vitae and names of 3 referees to Dr Fred Possmayer, Genetics Laboratory, Department of Biochemistry, University of Oxford, Oxford OX1 3QU, UK

(6841)A

ASSISTANT RESEARCH SCIENTIST

Research work on mechanism of folding and function of X-chromosome-linked enzyme, phosphoglycerate kinase, synthetic antibodies, genetically engineered protein to study relationship between biological functions and structures. Must have Ph.D. in Chemistry and be able to manipulate and maintain CD, NMR, UV-VIS and Spectroflourimeter.

Job site Duarte, California.
Salary: $25,000.00 per year.
Send this ad and your resumé to.

Job #5373, P.O. Box 865, Sacramento, CA 95804
not later than July 6, 1985

(NW1878)A

MOLECULAR BIOLOGIST

Tenure-track position at the assistant professor level for a molecular biologist. Applicant must have at least 2 years postdoctoral experience and demonstrated accomplishment in eukaryote gene expression studies. Expertise in recombinant DNA technology essential. Ph.D. or M.D. **Send curriculum vitae, a statement of research interest, and the names and addresses of 3 references to: Dr. Ralph Weichselbaum, Professor & Chairman, Dept. of Radiation Oncology, Biological Sciences Division, The University of Chicago, Box 440, 5841 S. Maryland Ave., Chicago, IL 60637.** An Affirmative Action Equal Opportunity Employer.

(NW1874)A

RESEARCH SCIENTISTS

California Biotechnology Inc., an established biotechnology company, is seeking scientists at the Ph.D. and M.S./B.S. levels to participate in exciting research programs. Qualified applicants should have experience in one of the following areas:

Protein and peptide chemistry with broad expertise in the purification, characterization, structural analysis, or synthesis of novel proteins and peptides.

Monoclonal antibody production with experience in both *in vivo* and *in vitro* techniques of hybridoma production.

Molecular pharmacology to study ligand-receptor interactions and coupling of receptors with intracellular mediators of action.

Molecular biology with experience in recombinant DNA techniques and the expression of foreign genes in bacteria, yeast, or mammalian cells.

We offer a comprehensive benefits package and competitive salaries. For consideration, please submit a curriculum vitae, a list of publications and the names of three references to:

PROFESSORIAL POSITIONS

Neurobiology Center
Mount Sinai School of Medicine
the City University of New York

Mount Sinai School of Medicine of CUNY announces a new initiative in molecular genetics. The Neurobiology Center plans to appoint groups of research scientists who are creatively attacking important biological problems using the most advanced techniques in molecular genetics.

We are seeking (an) established investigator(s), who will assume a leadership role, as well as applicants for assistant or associate professorships.

Please send inquiries and curriculum vitae to:

Dr. Kenneth L. Davis
Dept. of Psychiatry
Mount Sinai School of Medicine
1 Gustave L. Levy Place
New York, New York 10029 (NW1868)A

HERIOT-WATT UNIVERSITY

Department of Physics and Department of Electrical & Electronic Engineering

RESEARCH ASSOCIATE

Application of Optical and Electro-Optical Techniques to Computing

Applications are invited for the above interdepartmental research post, funded by Burroughs Machines Ltd and aimed at studying the likely future impact of laser, nonlinear optical and electro-optical technology on computer and information processing hardware

The succesful applicant will be based in the Physics Department and will work within a large group funded by the SERC, Industry and the EEC, working on nonlinear optics, optical bistability and all-optical computing concepts He/she will be expected to carry out experimental research of relevance to both these topics and digital electronic computers, such as the use of fibre-optic or holographic techniques for realising optical interconnections etc.

Candidates must have obtained a Ph D. in a field relating to at least osme of the areas indicated above The post will be tenable for an initial period of three years and the salary will start in the range £7,980 to £9,390 (under review) and includes yearly increments

For further details contact Dr. Andy Walker (031 449 5111). Application forms are available from the Staff Officer, Heriot-Watt University, Chambers Street, Edinburgh EH1 1HX quoting Reference No. 55/85.

(6872)A

THE UNIVERSITY OF LEEDS

DEPARTMENT OF ORGANIC CHEMISTRY

PROJECT ASSISTANT

Applications are invited for the above post in the Wolfson Unit for Computer Aided Design of Organic Synthesis The work requires a good knowledge of Organic Chemistry and involves the development of a reaction indexing database for use with a new computer program called ORAC

A good honours degree in Chemistry is required An interest in chemical applications of computers would be an advantage

The post is available immediately for a fixed term of up to one year. There may be the possibility of a further fixed-term contract thereafter.

Salary within the range £6,600-£8,920 on the IB Grade for Other Related Staff (£6,600-£10,330) (under review) according to qualifications and experience.

Informal enquiries may be made to Dr A P Johnson (tel 0532 431751 ext 6071/6058)

Application forms and further particulars may be obtained from the Registrar. The University, Leeds LS2 9JT, quoting reference no. 45/39 Closing date for applications 5 July 1985 (6875)A

UNIVERSITY OF DUNDEE

DEPARTMENT OF BIOCHEMISTRY

MRC PROTEIN PHOSPHORYLATION GROUP

RESEARCH ASSISTANT

(Postdoctoral or Postgraduate)

The successful candidate will work with Dr Grahame Hardie on the regulation of hepatic fatty acid synthesis by protein phosphorylation The study is supported by the MRC for 3 years and will involve studies of the phosphorylation of enzymes in iso lated hepatocytes treated with hormones or other agents (see Eur J Biochem (1984) 140, 325-333) The MRC Protein Phosphorylation Group consists of the laboratories of Professor P Cohen, Dr T Cohen and Dr Hardie and is extremely well equipped for this type of study The position is available immediately but persons who can start at any time up to January 1986 are invited to apply The appointment, which will be for one year in the first instance, will be on the Research Grade IA (£7,520 — £12,150) or IB (£6,600 — £8,920) depending on age, qualifications and experience

Informal enquiries may be made to Dr Hardie at the Department of Biochemistry (Dundee 23181 ext 4253) Applications, including curriculum vitae and the names of two referees, should be sent to the Personnel Officer, The University, Dundee, DD1 4HN as soon as possible. Please quote Ref. EST/70/85J. (6853)A

QUEEN MARY COLLEGE, UNIVERSITY OF LONDON

SCHOOL OF MATHEMATICAL SCIENCES

POSTDOCTORAL RESEARCH ASSISTANT IN APPLICATIONS OF COMPUTER ALGEBRA IN CATASTROPHE THEORY

Applications are invited for a research assistant to work for two years with Dr F. J. Wright, commencing as soon as possible after October 1, 1985. Experience in at least one of Computer Algebra and Catastrophe/Singularity Theory is desirable Salary on the Research and Analogous 1A scale £7,520-£12,150 per annum plus £1,233 London Allowance.

Further details may be obtained from Dr. Wright

Applicants should sent a curriculum vitae including list of publications (two copies) (and copies of any that are particularly relevant) and the names of two referees to the Assistant Personnel Officer, Queen Mary College, Mile End Road, London E1 4NS, and quote ref 85/43/N. The closing date is July 31, 1985.

Students interested in studying for a Ph.D. in this area are also invited to contact Dr Wright directly.

(6857)A

THE ROYAL VETERINARY COLLEGE

University of London

DEPARTMENT OF ANATOMY

POSTDOCTORAL RESEARCH ASSISTANT IN CELL BIOLOGY/ BIOCHEMISTRY

To work with Dr J. Bee on modifications of cell:cell interactions *in vitro* during loss of the cartilage phenotype and their implications to osteoarthritis Applicants should have an interest in cell biology or biochemistry of the cell surface, particularly intercellular junctions and cell communication. Experience in immunological methods is desirable, but not essential.

The appointment is funded by the Nuffield Foundation initially for twelve months with possible extension to three years.

Salary on the Universities' Research Scheme Grade 1A scale. Starting salary not less than £8,753 per annum including London Allowance. Superannuation under the Universities' scheme.

Application form obtainable from Assistant Secretary (Personnel), the Royal Veterinary College, Royal College Street, London NW1 0TU (Tel: 01-387 2898). (6856)A

STAFF RESEARCH ASSOCIATE MICROBIOLOGIST

Conducts research on particular aspects of physiological and morphological development of Bdellovibrio bacteriovirus, in collaboration with principal investigator. Must have demonstrated working knowledge of modern biochemical, microbiological & molecular biology techniques including isotope labelling & counting; ultracentrifuge; gel electrophoresis procedures & asceptic techniques; specimen preparation for electron microscopy thin sectioning techniques and modern electron microscope) in addition to experience in working with two-membered cultures. Ph.D. req. $1700/mo. Job located at educational institution in Los Angeles. **Send this ad and your résumé to Job #1724, P.O. Box 865, Sacramento, CA 95804 no later than 7/5/85. Must show you have the legal right to work.** (NW1875)A

POSTDOCTORAL RESEARCH POSITION in the University Medical Center Basic Science Department. Studies in cellular immunology of the function and development of human thymocytes and T-lymphocytes and on gene expression of lymphokine receptors. Experience in immunology, biochemistry and/or molecular biology desirable. Send résumé to: Joan Harmon, Personnel Department, NYU Medical Center, 560 First Avenue, New York, NY 10016. An Affirmative Action/Equal Opportunity Employer M/F. (NW1888)A

RESEARCH POST FOR A PHARMACOLOGIST

Horsham, West Sussex

A new position has arisen in the Pharmaceuticals Division of CIBA-GEIGY PLC for a Pharmacologist to join a group undertaking research into cardiovascular disease and its treatment.

The successful applicant will hold a degree in Pharmacology, or a related biological science with appropriate post-graduate experience in Pharmacology. A high degree of practical skill and the ability to work effectively within a multidisciplinary research group will be essential in this post.

An attractive starting salary is supplemented by a range of fringe benefits and conditions of employment which one would expect of a major international employer.

To help us assess your suitability for this post, please send in a letter of application together with a cv to:–

Miss S J Byrne, Personnel Officer, Ciba-Geigy Pharmaceuticals, Wimblehurst Road, Horsham, West Sussex RH12 4AB.

(6909)A

CIBA–GEIGY

EXCITING RESEARCH OPPORTUNITY IN WEST GERMANY

CELL BIOLOGIST

With experience in light and electronmicroscopic techniques and their application to immunological and biochemical studies at the cellular and sub-cellular level. The ideal candidate should have an MD and/or Ph.D, and postdoctoral experience.

In addition to the researcher's salary, this federally funded position includes salary for a Technician, start-up funds and an appropriate supply budget.

Please send CV and references to:
Dr. Rolf Kinne
Director Max-Planck-Institut fuer Systemphysiologie
Rheinlanddamm 201
4600 Dortmund 1, West Germany. (W1953)A

POSTDOCTORAL POSITIONS
HOWARD HUGHES MEDICAL INSTITUTE/ PHILADELPHIA

Fully funded postdoctoral positions in molecular biology and molecular genetics are now available at the Howard Hughes Medical Institute of the University of Pennsylvania. Active research projects include: transcriptional and translational control of eukaryotic gene expression, mechanisms of cellular transformation and gene amplification, molecular mechanisms of chromatin inactivation and the application of molecular genetics to studies of inherited disease.

For infomation please contact:
Dr. Steve Liebhaber, Coordinator
Howard Hughes Medical Institute
Department of Human Genetics
Medical Labs Building/G3
University of Pennsylvania School of Medicine
Philadelphia, PA 19104 (NW1869)A

UNIVERSITY OF ST ANDREWS
Department of Physiology and Pharmacology

(a) LECTURESHIP IN PHYSIOLOGY
(b) WELLCOME LECTURESHIP IN HUMAN MUSCLE PHYSIOLOGY

(a) Applications are invited for an established Lectureship in the above Department. Applicants should have a good research record in any field of experimental Physiology The Department occupies sites at the Bute Medical Building and Gatty Marine Laboratory. The successful candidate will be based at the Gatty Marine Laboratory and should have research interests which make full use of the facilities provided He/she will be required to contribute to the teaching of general Physiology to students. Current research interests of the Department include ion trans-port, neuropharmacology, muscle and environmental physiology.

(b) Applications are also invited from candidates under 35 years of age with a degree in Physiology or a related discipline, for a Lectureship in Human Muscle Physiology funded by the Wellcome Trust. The appointment is available for 3 years in the first instance renewable for a further 2 years The successful applicant will be required to contribute to the teaching of human and general physiology to students of physiology, pharmacology and physical education. The emphasis of this appointment will be on research and candidates are required to submit a 500 word summary of their proposed research schemes.

Salary at appropriate point on scale £7,520 — £14,925 per annum, starting salary probably not above £10,720 plus USS.

Further information about both posts may be obtained from the Department.

Applications (two copies preferably in typescript) in the form of *curriculum vitae*, statement of research interests and the names of three referees, should be lodged with the Establishments Officer, The University, College Gate, St Andrews, Fife, KY16 9AJ, NOT LATER THAN 5 JULY 1985. Candidates should indicated clearly which post(s) they are applying for.

(6844)A

BRISTOL POLYTECHNIC

SCIENCE DEPARTMENT

LECTURER II/SENIOR LECTURER IN PHYSICS

Applications are invited from good honours graduates in Physics or Applied Physics with post-graduate or industrial research experience Applicants should have an interest in aspects of Physics and Engineering related to scientific instrumentation and microprocessor technology. He/she will be encouraged to maintain a research activity in this or a related area

SALARY SCALE: LII £7,548-£11,175 (bar)—£12,099 per annum
SL £11,175-£13,128 (bar)—£14,061 per annum

The appointment will be made on the appropriate scale according to relevant previous service/experience. (Progression from the LII scale to the SL scale is in accordance with the provisions of the Burnham Further Education Report).

For further details and an application form, to be returned by 8 July 1985, please contact the Personnel Office, Bristol Polytechnic, Coldharbour Lane, Frenchay, Bristol or ring Bristol 656261, Ext 216 or 217.

Please quote Reference Number L/61 in all communications

Avon County Council is an Equal Opportunities Employer (6901)A

Applications are invited for a position in neurophysiology at the Assistant Professor level in the Department of Physiology at the University of Manitoba Faculty of Medicine. Candidates should have a PhD or equivalent, with two or more years of post-doctoral training. Preference will be given to individuals with experience and a continuing interest in electrophysiological analysis of neural networks and/or neurotransmitter actions using *in vitro* or *in vivo* systems. Send curriculum vitae, an outline of future research plans, and arrange for three letters of reference to be forwarded to. **Dr. Henry G. Friesen, Professor and Head, Department of Physiology, The University of Manitoba, 770 Bannatyne Avenue, Winnipeg, Manitoba, R3E 0WE Canada.** Deadline for receipt of applications is 1 September 1985 In accordance with Canadian immigration requirements this advertisement is directed to Canadian citizens and permanent residents. (NW1857)A

ORGANIC GEOCHEMIST

STANFORD UNIVERSITY

The School of Earth Sciences is intent on adding a new program in organic geochemistry and is seeking an individual with a solid geologic perspective to lead this effort Current research in all four departments in the School including Applied Earth Sciences Geology, Geophysics, and Petroleum Engineering involves work on sedimentary systems and we view organic geochemistry as an emerging tool of fundamental importance to these studies We also think that organic geochemistry constitutes a field of especially exciting potential for the future studies of the origin and fate of organic matter in modern and ancient sedimentary environments chemical fossils, sedimentary hosted mineral deposits petroleum geochemistry as well as applications to study of the tectonic and sedimentary evolution of continental margins

Applicants for this tenure-track position should have an established research record involving application of organic geochemistry to geological questions, an enthusiasm for teaching, and a clear ability to garner and maintain support for their research program We invite applications from both junior and senior scientists but we are most interested in finding a mid-career scientist of international reputation who is stimulated by the challenge of establishing a new program within the unusually diverse intellectual and geological environment offered by the San Francisco Bay region, Stanford University, and the School of Earth Sciences

Applicants should send a letter outlining their research and teaching interests along with vita including the names of three individuals familiar with their work to

Prof. James C Ingle, Chairman, Search Committee,
Department of Geology, School of Earth Sciences,
Stanford University, Stanford CA 94305

The level of this appointment is open and may be at Assistant, Associate, or Full Professor depending upon the individual selected Application deadline is September 30 1985

Stanford University is an Equal Opportunity Employer and we especially encourage applications from women and minority students (NW1882)A

PUBLIC HEALTH LABORATORY SERVICE BOARD

Central Public Health Laboratory

NATIONAL COLLECTION OF TYPE CULTURES

PLASMID COLLECTION

A Basic Grade MICROBIOLOGIST

(1st or 2nd class honours degree or postgraduate qualification) is needed by the National Collection of Type Cultures (NCTC) to complete a team of three whose task is to establish a service supply collection of plasmid bearing strains The work entails preservation, characterization, quality control and cataloguing and will initially concentrate on enterobacterial strains Previous experience in plasmid work an advantage.

NHS conditions of service apply

Salary scale £6,559 — £8,725 + £648 London Weighting

Further details and application forms from the Personnel Departments Central Public Health Laboratory, 61 Colindale Avenue, London NW9 5HT (6832)A

UNIVERSITY OF WALES COLLEGE OF MEDICINE

Tenovus Institute for Cancer Research

RESEARCH TECHNICIANS

required in the above Institute for work on various projects concerned with cancer research, some of which may have NHS involvement.

Salary scales and points will be dependent upon qualifications and experience, ranging from £4,531 to £7,159 per annum

Applications, in the form of a curriculum vitae with names and addresses of two referees, should be sent to Mrs Margaret Lewis, Tenovus Institute for Cancer Research, Heath Park, Cardiff, CF4 4XX as soon as possible. (6868)A

UNIVERSITY OF OXFORD

Dyson Perrins Laboratory

ORGANOMETALLIC CATALYSIS IN ASYMMETRIC SYNTHESIS

Applications are invited for post-doctoral work on a project concerned with the development of asymmetric catalysis and its use in the preparation of a range of optically active compounds, starting on October 1st 1985, or as soon as possible thereafter Those interested should write to Dr J M Brown, Dyson Perrins Laboratory, Oxford, OX1 3QY, UK, enclosing a full curriculum vitae and the names and addresses of two referees. Appointment will be for one year at this stage with the possibility of renewal, on the salary scale £7,520 — £7,980 pa, plus USS. (6865)A

UNIVERSITY OF SURREY

ROBENS INSTITUTE/ DEPARTMENT OF PHYSICS

WELLCOME LECTURESHIP

Applications are invited from medically orientated scientists preferably with a medical qualification, for the post of Wellcome Lecturer The post will be concerned with the development of Magnetic Resonance Imaging Techniques for the investigation of occupationally related disease. The successful candidate who will be based in the Robens Institute of Industrial and Environmental Health and Safety, will work in conjunction with the Department of Physics and will join a dynamic interdisciplinary team Facilities within the NMR Laboratory include a 1.5T intermediate scale imaging apparatus and a 0.15T whole body system The appointment is for three years, extendable to five years subject to review

Applicants should be under 35 years of age and should not be currently holding a tenured University post

Salary will be in the range £7,520 — £14,925 per annum (under review), according to age, qualifications and experience Superannuation under USS conditions.

For an informal discussion of the post please contact Dr L Hawkins (Robens Institute) or Dr D Taylor (Department of Physics) on Guildford (0483) 571281.

Further particulars are available from the Academic Registrar (AA), University of Surrey, Guildford, Surrey, GU2 5XH, or telephone Guildford (0483) 571281, Ext 633 Applications from men and women, in the form of a curriculum vitae, including the names and addresses of three referees, should be sent to the same address by 12 July 1985 quoting the reference 399/H (6835)A

UNIVERSITY OF ST ANDREWS

DEPARTMENT OF BIOCHEMISTRY AND MICROBIOLOGY

RESEARCH ASSISTANT IN BIOCHEMISTRY

Applications are invited for the above post, funded by the Multiple Sclerosis Society for two years. The successful applicant will be involved in the analysis of lipid peroxidation products in blood and CSF with a view to the development of a possible diagnostic test for MS. Some experience of HPLC, although not essential, would be an advantage.

Starting salary £6,600 pa on the 1B scale, plus USS

Applications, including full details of qualifications and experience plus the names of two referees, should be sent by 4th July 1985 to Dr M I S Hunter, Department of Biochemistry and Microbiology, University of St Andrews, Irvine Building, North Street, St Andrews, Fife, KY16 9AL, from whom further particulars may be obtained. (6886)A

THE AUSTRALIAN NATIONAL UNIVERSITY

Research School of Chemistry

POSTDOCTORAL RESEARCH POSITIONS

Applications are invited from suitably qualified men and women for appointment to postdoctoral research positions in the Research School of Chemistry

Current major research interests in the School are:

ORGANIC CHEMISTRY

(Professor A L J Beckwith, Professor L N Mander, Mr R W Rickards, Dr J K MacLeod, Dr L Radom): including free radical reactions; mechanistic and synthetic organic chemistry, reactive intermediates; organic and bio-organic chemistry of biologically active compounds, ICR and mass spectrometry; ESR spectroscopy; theoretical organic chemistry.

INORGANIC CHEMISTRY

(Professor B G Hyde, Professor A M Sargeson, Dr M A Bennett, Dr G B Robertson, Dr S B Wild): including solid state inorganic chemistry; synthesis, structure and reaction mechanisms of transition metal complexes; biomimetic chemistry; organotransition metal chemistry; X-ray crystallography; resolution and reactions of chiral arsines and phosphines.

PHYSICAL AND THEORETICAL CHEMISTRY

(Professor J W White, Dr J Ferguson, Dr R Bramley, Dr L R Brown, Dr T R Welberry, Dr D J Evans): Novel materials; low dimensional phenomena including interfaces; neutron scattering; spectroscopy and photochemistry; photophysics and magnetic resonance; NMR spectroscopy, structure and dynamics of macromolecules; X-ray diffraction and theoretical studies of disordered materials, liquid state chemical physics

CONDITIONS OF APPOINTMENT Appointments will be made at the levels of Postdoctoral Fellow and Research Fellow. The level appropriate for each appointee will be determined by the University and will depend on qualifications and experience Appointment as Postdoctoral Fellow will be for one or two years; appointment as Research Fellow will be for three years in the first instance Salary will be within the ranges: Postdoctoral Fellow $A22,614 — 25,905 pa; Research Fellow $A26,236 — 34,467 pa Current exchange rates are $A1:Stg 54p. $US 68c. $C 90c Grants are provided towards travel and removal. Assistance towards housing is given to an appointee from outside Canberra Eligible appointees will be required to join the Superannuation Scheme for Australian Universities Maternity leave is available. The University reserves the right not to make an appointment or to make an appointment by invitation at any time. Applicants should quote reference number RC 30.5.1 when submitting applications and when requesting further particulars, which are available from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H OPF, or from the Acting Registrar of the University, GPO Box 4, Canberra, ACT 2601, Australia.

There is no application form. Applicants should supply to the Acting Registrar of the University by 30 August 1985 a curriculum vitae, a list of publications, and statement of research interests, together with two passport-sized photographs, the names and addresses of three academic referees and the probable data on which the Postdoctoral Fellowship or Research Fellowship, if awarded, could be taken up.

The University is an equal opportunity employer. (W1961)A

SHROPSHIRE HEALTH AUTHORITY

THE ROBERT JONES & AGNES HUNT ORTHOPAEDIC HOSPITAL

Post Doctoral Principal Biochemist

DEPARTMENT OF RHEUMATOLOGY

Experience in protein biochemistry and immunology essential.

As well as providing a quality service of immunological investigations, there is an additional research element. Both aspects are closely integrated with clinical material.

Applications, stating age, qualifications and experience, together with the names of two referees should be sent to the Unit Administrator, The Robert Jones & Agnes Hunt Orthopaedic Hospital, Oswestry, Shropshire, within three weeks of this advertisement Further information may be obtained by contacting Dr D J Ward, Consultant Rheumatologist. (6884)A

THE UNIVERSITY OF MANCHESTER

POSTDOCTORAL RESEARCH POST IN THE

DEPARTMENT OF ANATOMY

Applications are invited for this three-year post, funded by the Medical Research Council, to undertake experiemental studies into Parkinson's Disease The work will involve stereotaxic surgery, deoxyglucose metabolic mapping, receptor binding autoradiography and neuroanatomical tracing techniques. Previous experience in one or more of these would be a distinct advantage The post is available from October 1st, 1985.

Initial salary up to £8,920 pa. Superannuation.

Applications, including the names of two referees, should be sent as soon as possible to Dr A R Crossman, Department of Anatomy, The Medical School, The University, Manchester M13 9PT (6839)A

Imperial Tobacco Limited, the UK's leading tobacco products manufacturer, seeks a suitably qualified scientist to join its Research Team.

INDUSTRIAL TOXICOLOGIST

Bristol **£11,500–£13,800**

This position offers an excellent opportunity for a young graduate specialist with flair and creative skills to act in an advisory/consultative capacity on a wide range of the Company's activities including Health and Safety at Work. The successful candidate will also be expected to keep abreast of any new developments and applications in methodology and mathematical modelling.

Candidates should ideally have a post-graduate qualification or at least a first-class honours degree in physiology, pathology, genetics or other relevant discipline, together with recent experience in toxicological research.

We offer a progressive salary within the range £11,500–£13,800 dependent on experience, together with an excellent range of benefits and staff facilities.

Please send full CV or write/telephone for an application form to A. W. L. Mortimore, Personnel Services, P.O. Box 244, Hartcliffe, Bristol BS99 7UJ. Tel. Bristol (0272) 781111 Ext 2206

IMPERIAL TOBACCO LIMITED

Imperial Tobacco Limited

Imperial Tobacco is an equal opportunity employer.

ETH ZÜRICH

Applications are invited for faculty positions in

Plant Biochemistry

at the Swiss Federal Institute of Technology in Zurich.

One or two faculty positions are available in the Faculty of Natural Sciences. The successful applicants are expected to develop their own research program and to participate in teaching basic biology to students of biology, forestry and agricultural engineering, rural engineering and pharmacy. For the advanced biology students the new professors will teach the field of their own research.

The applicants should have a Ph.D. and should have performed several years of independent research, preferably in the fields of plant physiology or developmental plant biology. They should be talented and willing to teach at all university levels.

Applications with curriculum vitae and list of publications should be submitted not later than July 15, 1985, to:

The President of ETH Zurich
Prof. H. Ursprung
ETH-Zentrum
8092 Zurich
Switzerland. (W1959)A

RESEARCH ASSOCIATE and RESEARCH SPECIALIST

positions for conducting research on genetic aspects of biodegredation of hazardous chemicals. Postdoctural Research Associates (Ph D) must have experience in recombinant DNA techniques as well as in DNA sequencing.

One Research Associate will work jointly with the University of Illinois at Chicago and an environmental research team in microbial ecology-biotechnology at the U.S EPA Laboratory in Gulf Breeze, Florida The other Research Associate and the Research Specialist (B S) will work jointly with the EPA Hazardous Waste Engineering Laboratory in Cincinnati, Ohio.

Send resumés and other details to

CENTRAL MANCHESTER HEALTH AUTHORITY
ST MARY'S HOSPITAL
DEPARTMENT OF MEDICAL GENETICS
Immunogenetics Laboratory
GRADUATE SCIENTIFIC OFFICER

Required to work with Dr G M Taylor on the development of Immunogenetic techniques for the diagnosis of Down's Syndrome, funded by N W Regional Health Authority The project involves the analysis of cell-surface antigen expression by Down's cells.

Experience in any of the following would be advantageous; preparation of monoclonal antibodies, cell culture, cytogenetics or fluorescence flow cytometry

The position is available for one year in the first instance, with an extension up to three years. Salary up to £7,311 pa according to qualifications and experience.

Applications with names of 2 referees and informal enquiries to Dr G M Taylor, Department of Medical Genetics, St Mary's Hospital, Whitworth Park, Manchester M13 0JH Tel: 061-276 6472/6499. Closing date 30th June 1985. (6900)A

UNIVERSITY COLLEGE CORK
RESEARCH POSITIONS IN MICROBIOLOGY/ BIOTECHNOLOGY
POSTDOCTORAL RESEARCH ASSOCIATES

(2) to work on projects involving molecular genetics of plant-microbial interactions —

(A) to investigate genes involved in carbon metabolism in Rhizobium (Genetic Engineering);
(B) to investigate the regulation of carbon metabolism in Rhizobium and plant growth promoting Pseudomonas spp. (biochemical-genetics/physiology)

Positions are available from 1 July 1985 and salary will be in the range IR£8,596-IR£11,173 (less PRSI contribution) according to experience

Applications including a C.V and the names of two referees should be sent as soon as possible to Dr F. O'Gara, Microbiology Department, University College, Cork, Ireland, from whom further particulars are available. (6903)A

UNIVERSITY COLLEGE LONDON
DEPARTMENT OF BIOCHEMISTRY
TWO POSITIONS

are available in a group working on the DNA sequences that direct heat-shock activation of the yeast gene for 3-phosphoglycerate kinase. Both are tenable initially for 3 years and are funded by the SERC Biotechnology Directorate. One appointment will be made at

Post-Doctoral (RESEARCH ASSISTANT IA)

level and the other at

TECHNICIAN (GRADE 3)

level. Experience in cloning and/or M13 sequencing would be preferable.

Applications for either the post-doctoral or technician posts should be sent to Dr P W Piper, Department of Biochemistry, University College London, Gower Street, London WC1E 6BT (Tel: 01-387 7050 extn: 291), to arrive not later than 31 July 1985. They should include a cv and the names and addresses of two referees (6858)A

LEUKAEMIA RESEARCH FUND CENTRE AT THE INSTITUTE OF CANCER RESEARCH:
TECHNICIAN/RESEARCH OFFICER

required to help organise a molecular biology laboratory and actively participate in its research programme into Cellular and Molecular Biology of Human Leukaemia. Experience in recombination DNA techniques essential. Candidates should have a degree, HNC or equivalent qualification.

Salary will be in the range of £5,738 — £8,096 + £1,042 pa. London Weighting allowance, depending on qualifications and experience. Applicants are advised that in the majority of the Institute's premises smoking is prohibited

Applications in duplicate with the names and addresses of two referees should be sent to the Personnel Officer, Institute of Cancer Research, 17A Onslow Gardens, London SW7 3AL, quoting reference 301/B/86. (6862)A

THE UNIVERSITY OF MANCHESTER
Theoretical Chemistry Group
ICI JOINT RESEARCH SCHEME

A Postdoctoral position is available for a two year period for a theoretical chemist or physicist to participate in a fundamental quantum-statistical study of the effect of high pressures on the electronic stucture of molecules and molecular processes occuring in detonation. The work will be under the direction of Professor W Byers Brown and will be carried out in collaboration with the Detonation Research Group, ICI plc, Ardeer. Applicants should have experience of computational quantum chemistry techniques and preferably also with statistical perturbation theories. Salary on the IA Range for Research and Analogous Staff (£7,520 — £12,150 pa) according to age, qualifications and experience.

Scientific enquiries and applications to Professor W Byers Brown (061-273-7171 Ext: 5286), Department of Chemistry, The University, Manchester M13 9PL. (6894)A

UNIVERSITY OF THE WEST INDIES
Mona, Jamaica
SENIOR LECTURER/ LECTURER IN ORGANIC CHEMISTRY

Successful applicant will be expected to participate in the teaching and organisation of the courses in the Department and to contribute to its research programme.

Salary scales (under review): Senior Lecturer J$29,532 × 825 — 33,657 × 924 — 36,429 (B) × 924 — 37,353 × 987 — 38,340 Lecturer J$23,688 × 768 — 28,296 (B) × 825 — 33,246.

Up to five full economy class passages plus baggage allowance up to US$900 on appointment and normal termination. Special allowance up to US$300 for shipment of academic books and teaching/research equipment on appointment Unfurnished accommodation at 10% of pensionable salary or housing allowance of 20% of pensionable salary. UWI contribution of equivalent of 10% of salary to Superannuation Scheme. Subsidized Health Service. Annual Book Allowance Annual Study and Travel Grant for self, spouse and three children. Transportation allowance to persons who own and operate a motor vehicle.

Detailed applications (three copies) giving full particulars of qualifications and experience, date of birth, marital status, and the names and addresses of three referees should be sent as soon as possible to the Campus Registrar, UWI, Mona, Kingston 7, Jamaica, West Indies. Applicants in the UK should also send one copy to the Secretary General, Association of Commonwealth Universities (Appts). 36 Gordon Square, London WC1H 0PF. Further details obtainable from either source. (W1965)A

UNIVERSITY OF LEICESTER
DEPARTMENT OF ZOOLOGY
RESEARCH ASSISTANT (GRADE 1B)

Applications are invited for an SERC-funded Research Assistantship to use DNA "mini-satellite fingerprinting" in studies of the ecology and behaviour of vertebrates.

Applicants should have some laboratory experience of DNA technology and should have or expect to obtain a good honours degree in an appropriate field of Biological Science. The post is for one year, commencing as soon as possible after July 1, 1985. Salary £6,600-£8,920.

Applications, together with a *curriculum vitae* and the names of two academic referees, should be sent as soon as possible to Professor H. C. Macgregor, Department of Zoology, University of Leicester, Leicester LE1 7RH.

Further information can be obtained by phone from Dr T. Burke at 0533-554455 extns. 323 or 115. (6874)A

SCHOOL OF HERBAL MEDICINE — PHYTOTHERAPY
PART-TIME LECTURESHIPS IN PHYSIOLOGY AND PATHOLOGY

Two lecturers are required for one day per week to lecture in physiology and pathology to students studying for the Diploma in Phytotherapy (Dip Phyt). The posts would be of particular relevance to lectures interested in the application of scientific disciplines to the study of phytotherapy

For further details apply to: The Principal; School of Herbal Medicine — Phytotherapy, 145 Forest-Road, Tunbridge Wells, Kent. (6849)A

POSTDOCTORAL MOLECULAR BIOLOGIST

Position available immediately to join active group studying the molecular genetics of RNA splicing in *E coli* Background in RNA processing and/or microbial genetics desirable Experiments conducted in a well-equipped research facility Salary competitive and commensurate with experience

Send curricumum vitae, description of future professional goals and names of three references to

Dr Marlene Belfort
Wadsworth Center for Laboratories and Research
New York State Department of Health
Empire State Plaza
Albany, NY 12201

(NW1892)A

UNIVERSITY OF NOTTINGHAM

LECTURESHIP IN PHYSICS

NMR IMAGING

Applications are invited for a Lectureship in Physics. The post is designed to strengthen research in the applications to medicine and biology of nuclear magnetic resonance imaging techniques The person appointed will work closely with Professor Mansfield on a large project supported by the Medical Research Council and the D H S S Experience in NMR is desirable but not essential. Knowledge of digital-electronics,. computer control, fast data processing, image analysis would also be relevant The lecturer will be expected to contribute to teaching of these as well as traditional physics subjects

Salary will be in the range £7,500 to £14,925 per annum.

Further particulars and application forms, returnable not later than 5 July 1985, may be obtained from the Staff Appointments Officer, University of Nottingham, University Park, Nottingham NG7 2RD Ref No. 1001. (6878)A

VIRAL IMMUNOLOGIST

The Lady Davis Institute for Medical Research, in affiliation with McGill University, has a position for an independent investigator at the Assistant Professor level. Candidates should hold an MD or PhD degree and have at least two years of post-doctoral experience.

Please send curriculum vitae, list of publications, a short description of proposed research and names of three referees to Dr N Kalant, Director, Lady Davis Institute for Medical Research, 3755 Cote St, Catherine Road, Montreal, Quebec, Canada H3T 1E2.

In accordance with Canadian Immigration regulations applications from Canadian citizens and landed immigrants will be considered first. (NW1872)A

UNIVERSITY OF BRISTOL

DEPARTMENT OF PHYSIOLOGY

Applications are invited for the post of

LECTURER IN PHYSIOLOGY

The Department is particularly seeking a physiologist who is a veterinary graduate. It would, however, also be interested in receiving applications from candidates with a medical degree or a research interest in cardiac muscle. The salary will be within the range £7,520 - £14,925 per annum together with superannuation.

Applications including the names and addresses of two referees, should be sent by 28th June 1985, to the Registrar and Secretary, University of Bristol, Senate House, Bristol BS8 1TH, from whom further particulars may be obtained. Please quote reference TLJ. (6772)A

MOLECULAR IMMUNOLOGY POST-DOCTORAL SCIENTIST

Salary from £9,000

Celltech, a leader in the field of biotechnology, has achieved its present success in the space of five years. Pioneers in several areas, our achievements are based on the foundations of scientific excellence, innovation and commercial expertise.

Celltech's Molecular Immunology group is expanding its activities in the molecular cloning and expression of immunological targets, principally antibodies. We are looking for a Molecular Biologist/Immunologist, either a post-doc or a graduate expecting soon to finish a PhD. Experience in molecular or cellular immunology would be desirable

We are an ambitious and forward looking company, which places as much emphasis on its people as its products. You will work in a small friendly team, gaining invaluable broad-based experience, with plenty of opportunity for advancement.

Please send a detailed c.v. to Jane Walley, Celltech Ltd., 244–250 Bath Road, Slough, Berks SL1 4DY, quoting Ref. 268.

CELLTECH

UNIVERSITY OF CAMBRIDGE

DEPARTMENT OF PATHOLOGY

DIVISION OF IMMUNOLOGY

Applications are invited for a

POSTDOCTORAL RESEARCH ASSISTANT

to join a group working on the immune response to neurotropic viruses. The successful applicant will work on the immune response to Theiler's virus infection — an unusual persistent virus infection of the central nervous system. Candidates should hold or expect to obtain a doctorate in the field of cellular immunity, and have an interest in viral immunology.

The appointment, which is financed by a grant from the Multiple Sclerosis Research Fund is for 3 years.

Age range 24-27, Salary range £7,520–8,450 under review.

Formal applications, including the names and addresses of two referees should be sent to The Superintendent, Department of Pathology, Tennis Court Road, Cambridge CB2 1QP. Telephone enquiries to Dr A Nash (0223) 64631 (6870)A

UNIVERSITY COLLEGE CORK

RESEARCH POSITIONS IN MICROBIOLOGY/ BIOTECHNOLOGY

POSTDOCTORAL RESEARCH ASSOCIATES (2)

To work on projects involving molecular genetics of plant-microbial interactions —

(a) To investigate genes involved in carbon metabolism in rhizobium (Genetic Engineering):

(b) To investigate the regulation of carbon metabolism in Rhizobium and plant growth promoting pseudomonas SPP (Biochemical-Genetics/ Physiology)

Positions are available from 1 July 1985 and salary will be in the range - IR£8,596 — IR£11,173 (less PRSI contribution) according to experience.

Applications including a cv and the names of two referees should be sent as soon as possible to Dr F O'Gara, Microbiology Department University College, Cork, Ireland, from whom further particulars are available. (6885)A

GREATER GLASGOW HEALTH BOARD

Royal Hospital for Sick Children, Yorkhill, Glasgow G3 8SJ

DUNCAN GUTHRIE INSTITUTE OF MEDICAL GENETICS

PRINCIPAL SCIENTIFIC OFFICER

This is a new fixed term appointment for three years in the first instance made through a grant from New Developments in Health Care in order to develop molecular genetics laboratory services within NHS in Scotland The successful candidate will be expected to help in the development of DNA Analysis for the diagnosis and carrier detection of genetic disease

Candidates should have an honours degree in Genetics, Molecular Biology or related discipline Postgraduate experience in molecular genetics is essential.

Application Form and Job Description available from Personnel Office, Royal Hospital for Sick Children, Yorkhill. Telephone 041 339 8888 extension 517

Closing Date 5 July 1985.

(6833)A

UNIVERSITY OF DUBLIN
Trinity College

DEPARTMENT OF MICROBIOLOGY

RESEARCH FELLOW

Applications are invited for the above post in the Department of Microbiology at Trinity College, Dublin.

The appointment which will be tenable for a period of two years, will involve molecular cloning and site-directed mutagenics of virulence determinants of bovine isolates of **Staphylococcus aureus.**

Salary: IR£8,500 per annum.

Intending candidates should submit a full curriculum vitae, together with the names of two referees to

Dr. T. J. Foster,
Department of Microbiology,
Moyne Institute,
Trinity College, Dublin 2

to arrive not later than **31st July, 1985.** (6887)A

ASSISTANT PROFESSOR

Applicants are being sought to fill an assistant professorial position to work on leishmaniasis in the Department of Medicine, Division of Tropical Medicine, of Harvard Medical School.

Applicants should have expertise in cellular immunology and experience in working with these organisms The person would be expected to establish a vigorous research and teaching program

Applicants should send a curriculum vitae, bibliography, copies of publications, names and addresses of three referees and a summary of both research and teaching objectives to

John R David, M.D.,
Seeley G. Mudd Building
250 Longwood Avenue
Boston, Massachusetts 02115

Harvard is an equal opportunity/ affirmative action employer Applications from women and minorities encouraged (NW1889)A

UNIVERSITY OF KENT
AT CANTERBURY

Biological Laboratory
Readership/Senior Lectureship in Mammalian Biochemistry

Following the election of Dr R B Cain to a Chair in the University of Newcastle, applications are invited for the above post The requirement is for a biochemist with a strong research record who will take a leading role in planning and implementing developments in mammalian biochemistry. The post is offered on a permanent basis and the salary will be on the Reader/Senior Lecturer scale: £14,135 — £17,705 per annum.

Forms of application and further particulars of the post may be obtained from the Assistant Registrar, Faculty of Natural Sciences, Chemical Laboratory, The University, CANTERBURY, Kent CT2 7NH.

Closing date 19 July 1985. Please quote ref A42/85/N (6899)A

UNIVERSITY OF NEWCASTLE UPON TYNE
DEPARTMENT OF BIOCHEMISTRY
POSTDOCTORAL RESEARCH ASSOCIATE

Applications are invited for an SERC funded post to work on the mechanisms by which globular proteins fold into their active state. Spectroscopic, scattering, hydrodynamic and monoclonal antibody techniques will be used to study naturally occurring, mutant and recombinant proteins The appointment is for three years tenable from September 1985 or soon after

Salary will be up to £7,980 per annum on the Range 1A salary scale: £7,520 — £12,150 per annum according to age, qualifications and experience.

Candidates with PhD or expecting to have gained a PhD by the autumn should send applications with curriculum vitae and the names and addresses of three referees to Professor R H Pain, Department of Biochemistry, University of Newcastle upon Tyne, NE1 7RU by July 18th. (Telephone 0632 328511 Ext 3437). (6891)A

UNIVERSITY OF BRISTOL
Tsetse Research Laboratory, Langford
ENTOMOLOGIST

Applications are invited for a three year postdoctoral appointment funded by the Overseas Development Administration at the Tsetse Research Laboratory, Langford (12 miles south of Bristol) The successful candidate will be expected to undertake laboratory research into the sexual behaviour of tsetse flies in relation to visual and chemical stimuli with a view to improving trapping techniques in the field

Considerable automation of data collection is anticipated and interest/ experience in electronics and microcomputers will be an advantage Position available from 1st October, 1985 Salary on 1A Scale within range £7,520 — £8,920 according to age.

Reply, with curriculum vitae and the names of two referees, by 31st July 1985 to Dr P A Langley, Tsetse Research Laboratory, Langford House, Langford, Bristol, BS18 7DU (6846)A

BIRKBECK COLLEGE
(University of London)
POSTDOCTORAL RESEARCH ASSISTANT
LABORATORY OF MOLECULAR BIOLOGY, DEPARTMENT OF CRYSTALLOGRAPHY

Applications are invited to work on a project funded jointly by the SERC and Pfizer UK ltd, to study cAMP phosphodiesterase enzymes from heart muscle as a basis for rational drug design The project will involve protein purification, microsequencing, cDNA preparation and computer graphics modelling The applicants should have experience in at least two of these areas The post is available immediately

Salary on the RA1A scale for research staff (£7,520 — £12,150 + £1,233 pa London Allowance)

Applications including curriculum vitae and the names of two referees should be sent to the Assistant Secretary (Personnel), (PRC), (N), Birkbeck College, Malet Street, London WC1E 7HX by 30th June 1985. Enquiries to Professor T L Blundell, FRS, at the above address or on 01-580 6622 ext: 284. (6883)A

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE
(University of London)
Keppel Street, WC1E 7HT.
PREVENTIVE TERATOLOGY UNIT

Applications are invited for a
MEDICAL LABORATORY SCIENTIFIC OFFICER IN BIOCHEMICAL TERATOLOGY

to work on congenital malformations associated with environmental agents

The appointment is for 14 months at a salary, depending on age, experience and qualifications, on a scale which rises to £6,726 plus £1,042 London Weighting per annum

Applications, stating qualification and experience and the names of two referees, should be sent to the Assistant Personnel Officer at the School, quoting reference (N1). Closing date July 10th 1985. (6855)A

THE UNIVERSITY OF MANCHESTER
DEPARTMENT OF BACTERIOLOGY AND VIROLOGY
POSTDOCTORAL RESEARCH ASSOCIATE

Applications are invited for this post to work on the obligate intracellular prokaryotic, Chlamydia trachomatis. This MRC funded study involves an investigation of intracytoplasmic events related to persistence of infection within cultured eukaryotic cells. Applicants with training in either cell biology or microbiology will be considered; experience of cell culture techniques is highly desirable Initial salary range £7,520 — £8,450 pa Superannuation Position available from October 1985 for 3 years Enquiries for further details, and applications including CV and names of 2 academic referees, to Dr Shirley Richmond, Department of Bacteriology and Virology, The University, Manchester M13 9PT (6892)A

MONASH UNIVERSITY
Melbourne, Australia
CHAIR OF EARTH SCIENCES

Applications are invited for the position of Professor in the Department of Earth Sciences An innovative scientist with a strong research reputation is sought to guide future development

Established in 1972 Earth Sciences has gained recognition for the quality of its graduates and its research With ten academic and eight technical staff, it covers a wide range of teaching and research areas The Department is well equipped for experimental and analytical studies and has strong field-based interests. Involved in joint research with other university departments, industry, and government agencies, it attracts funding from both Australian and overseas granting bodies The international postgraduate research group includes six post-doctoral workers, thirty PhD and ten MSc students

Areas covered by the Department's current activities include igneous, metamorphic, and are petrology/geochemistry, structural geology, sedimentology and volcanology palaeoclimatology, palaeontology, isotope and solution geochemistry, regional geology, and tectonics. A geophysics teaching and research program will commence shortly with the appointment of two academic staff Workers in the above fields, or in any of the more quantitative aspects of the earth sciences, will find a stimulating research environment, but applications from those with other interests will be considered The successful applicant must have outstanding leadership qualities and the ability to interact positively with industry

Enquiries about the Department may be directed to Dr Ian Nicholls, Acting Chairman

Salary, $A54,948 pa. Superannuation, travel and removal allowance, and temporary housing assistance.

Information on application procedure and further particulars may be obtained from the Registrar, Monash University, Clayton, Victoria 3168, Australia, or the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF

Applications should reach the Registrar not later than 23 August 1985 Council reserves the right to make no appointment or to appoint by invitation at any stage

An equal opportunity employer (W1960)A

nature
when replying to these advertisements

POSTDOCTORAL POSITION

available immediately in research-intensive department for Ph.D. in biochemistry, cell or molecular biology, or immunology Research deals with the mechanism of action at the receptor and postreceptor level of polypeptide growth factors that induce cellular transformation and differentiation.

Experience in the following areas is desirable: Receptor biochemistry; hybridoma technology, protein and peptide purification, hormonal regulation of gene expression

Send curriculum vitae and names of three references to.

Dr J. Massague
Department of Biochemistry
University of Massachusetts Medical School
55 Lake Avenue North
Worcester, Massachusetts 01605

An Equal Opportunity/Affirmative Action Employer. (NW1891)A

RESEARCH POSITIONS

1) Postdoctoral Associate and 2) Research Assistant (BS or MS) positions available in a research group working with RIBOSOMAL PROTEIN GENES AND cDNA EXPRESSION LIBRARY from higher plants DNA cloning and/or sequencing experience required. Write to: Dr Alap Subramanian, Group Leader, Max-Planck-Institut fur Molekulare Genetik, Abt Wittmann, Ihnestr 63, Berlin-Dahlem, Fed Rep Germany. (W1933)A

GRANTS & SCHOLARSHIPS

IMPERIAL CANCER RESEARCH FUND

BURSARY FOR TRAINING IN RESEARCH

Applicants are invited for an ICRF Bursarship tenable for 3 years from October 1985 for full time students leading to a higher degree in biochemistry. The bursarship offers the opportunity to join an active cell membrane research group in the Department of Biochemistry, at the Royal College of Surgeons, in collaboration with the Cell Surface Biochemistry Laboratory, ICRF

The research topic, which will be jointly supervised by Professor N Crawford and Dr M Crumpton (ICRF), involves investigating procedures for permeabilising blood cells and their use as carrier vehicles with encapsulated drugs and other agents which activates macrophages for sustained tumourcidal effects

Applications are invited from students, no more than 25 years of age on October 1st who hold, or expect to obtain a First or Upper Second Class Honours degree in Biochemistry or Cell Biology. The award carries a grant of £4,865 with possible additional allowances.

Further details and application forms can be obtained from: Miss S M Hurley, Personnel Officer, Imperial Cancer Research Fund, Lincoln's Inn Fields, London, WC2A 3PN.

Please quote reference number: 85/85.

The forms should be completed and returned by 31st July 1985. (6904)H

ASSISTANTSHIPS

UNIVERSITY OF CAMBRIDGE

UNIVERSITY CHEMICAL LABORATORY

POSTDOCTORAL ASSISTANTSHIP

Applications are invited from molecular biologists for work on the cloning and expression of the genes for the key enzymes on the biosynthetic pathways to haem, vitamin B_{12} and related macrocycles This will be in collaboration with Dr C Abell and Professor A R Battersby

The appointment from a mutually agreed date in 1985 is for up to 2 years at a starting salary within the Scale £7520 (for 24 years of age) to £8920 (for 27 years of age) with an increment after one year. Applications with curriculum vitae and 2 referees' names should be sent as soon as possible to Professor A R Battersby, University Chemical Laboratory, Lensfield Road, Cambridge, CB2 1EW (6812)P

UNIVERSITY OF ABERDEEN

DEPARTMENT OF MICROBIOLOGY

POSTGRADUATE RESEARCH ASSISTANT

MOLECULAR MECHANISMS OF POTASSIUM TRANSPORT IN ESCHERICHIA COLI

The above SERC-funded Research Assistantship is offered for three years in the laboratory of Dr Ian Booth. The project will involve the use of advanced genetic techniques and gene cloning to study the mechanisms of regulations of potassium accumulation in E coli.

Salary on Range IB scale for Research and Analogous Staff £6,600 per annum, (scale under review).

Further particulars and application forms from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by 11 July 1985 (Ref No ED/006). (6888)P

SEMINARS & SYMPOSIA

AN INTERNATIONAL SYMPOSIUM ON PULMONARY EMPHYSEMA AND PROTEOLYSIS

14 to 16 January 1986
Pasadena, California

State-of-the-art presentations will be given on the protease-antiprotease balance in the lung, oxidant-antioxidant interactions and their influence on proteases, cigarette smoke components, tissue injury and inflammation, therapeutic approaches to emphysema, and genetic polymorphisms and deficiencies and their effect on disease. A full symposium volume will be published.

Attendance is limited. For more information and application, please write to: Charles Mittman, M.D., City of Hope Medical Center, 1500 East Duarte Road, Duarte, Calif. 91010.

(NW1876)M

FIRST ANNOUNCEMENT

4th International Symposium on the Biology of the

'VASCULAR ENDOTHELIAL CELL'

Noordwijkerhout, The Netherlands, 19-23 August 1986

This meeting is the fourth in a series, which began with a symposium at Cold Spring Harbor in May 1980. It will be organised in co-operation with the Netherlands Organization for Applied Scientific Research (TNO).

Chairman: P. Brakman, Ph. de Groot, V. W M. van Hinsbergh, W J C. Melgert, J. A van Mourik

In conjuction with the symposium a display of industrial firms will be organized.

Papers can be presented either by post or orally.

For information write to

TNO Corporate Communication Department, P.O. Box 297, 2501 BD DEN HAAG, The Netherlands (W1963)M

UNIVERSITY OF ABERDEEN

DEPARTMENTS OF BIOCHEMISTRY AND MEDICINE

RESEARCH ASSISTANTSHIP

THE INFLUENCE OF DIETARY POLYPHENOLS ON THE FIBRINOLYTIC OF MAN

Applications are invited for the post of Research Assistant to work with Professor D Ogston and Dr S B Wilson. The project will involve an assessment of the influence of polyphenols present in food and beverages on the fibrinolytic system of man and an identification of the compounds concerned. The post has been funded by the Scottish Home and Health Department for two years Applicants should have an Honours degree in Biochemistry or a related topic and may register for a higher degree if so desired

Salary within range £6,600-£7,980 per annum on the Range 1B Scale for Research and Analogous Staff with appropriate placing (scale under review)

Further particulars and application forms from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by 12 July 1985 (Ref No EL/008). (6902)P

UNIVERSITY OF DUNDEE

DEPARTMENT OF BIOLOGICAL SCIENCES

RESEARCH ASSISTANTSHIP

tenable for two years in the first instance at the Post-Graduate/Post-Doctoral level to work in collaboration with Dr C A B Jahoda and Dr R F Oliver on a skin biology project with applied potential.

We are seeking a biochemist with interest or experience in growth factors to study the control of cell proliferation in hair growth (ref. Nature, 311, 560-62, 1984).

Salary will be dependent of qualifications, age and experience within the range £6,600 — £8,920 per annum (pay award pending).

Applications containing a full curriculum vitae and the names and addresses of 3 referees should be sent as soon as possible to the Personnel Officer, The University of Dundee, Dundee, DD1 4HN. Please quote reference EST/60/85(J) (6843)P

continued on page 18

FELLOWSHIPS

ALL SOULS COLLEGE
RESEARCH FELLOWSHIPS

All Souls College intends to make elections to two Research Fellowships in the course of the academic year 1985-6.

The Research Fellowships are open to men and women whose work lies in following fields of study: Law, History, Philosophy, Politics, Economics, English Language and Literature, Classical Studies, Mathematical Sciences. The College would not normally elect to a Research Fellowship any person who will have reached the age of 40 on 1st March 1986.

The Research Fellowships will be tenable for a period of seven years in the first instance, and may be extended for a further period of not more than three years. On the expiry of the Research Fellowship, a Research Fellow who produces evidence of satisfactory achievement may apply to be considered for election to a Senior Research Fellowship.

Further particulars, including details of stipend and terms of appointment, and application forms, may be obtained from the Warden's Secretary, All Souls College, Oxford. Applications, on the application form, must reach the Warden not later than 19th October, 1985. (The envelope containing the application should be marked "Research Fellowship".) Applicants must ensure that references, from not more than three referees, also reach the Warden by 19th October 1985. (6873)E

BRITISH JOURNAL OF EXPERIMENTAL PATHOLOGY
FELLOWSHIP

The British Journal of Experimental Pathology is offering a Fellowship in the field of Experimental Pathology, to be awarded competitively at the end of 11985 and to be held during the years 1986, 87 and 88 The objective is to enable younger academic pathologists, whether medically qualified or not, to be freed from service, teaching and administrative duties fsor a period of three years Preference will be given to applicants under the age of 35 years The Fellowship carries a stipend commencing at the bottom of the Lecturer scale and an allowance for research expenses will also be made

The closing date is 8 August 1985 Further particulars may be obtained from

The Secretary to The British Journal of Experimental Pathology
Professor N Woolf
c/o The Bland-Sutton Institute of Pathology
The Middlesex Hospital Medical School
London W1.

The Fellowship is confined to applicants from institutes within the United Kingdom (6869)E

EMBO
European Molecular Biology Organization
LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY
Autumn 1985 — Awards
Next deadline: 15 August 1985

EMBO long term post-doctoral fellowships are awarded to promote the development of molecular biology and allied research in Europe and Israel To be eligible a candidate must hold a doctorate degree and the exchange must involve a laboratory in Western Europe or Israel. EMBO fellowships are not, however, awarded for exchanges between laboratories within any one country Long term fellowships are awarded initially for one year, but depending on a review of progress, they may be renewed for a second year In cases of exceptional scientific merit renewal for a third year is possible. The fellowship comprises a return travel allowance for the fellow and any dependents and a stipend and dependents' allowance.

Since the selection procedure may include an interview, candidates are requested to respect the deadline for complete applications which is 15 August 1985. Successful candidates will be notified of their awards immediately after the meeting of the selection committee, which is on 21 October 1985.

Application forms and further details may be obtained from Dr. J. Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 1022.40, 69 Heidelberg 1, F. R Germany. (W1893)E

UNIVERSITY OF ST ANDREWS

DEPARTMENT OF BIOCHEMISTRY AND MICROBIOLOGY

POST DOCTORAL FELLOWSHIP

Applications are invited for a Research Fellowship funded by the Medical Research Council to study recognition signals in adenovirus replication. The applicant should prefereably have some experience in either cloning or hybridoma technology and will become part of the Molecular Virology Group in the Department. The project will be under the supervision of Professor W C Russell from whom further information may be obtained (Telephone 0334 76161 ext 295).

The appointment will be for 3 years, starting as soon as practicable. Starting salary at appropriate point within range £7,520 to £10,330 per annum on the 1A Research scale, plus superannuation.

Applications (two copies preferably in typescript) with the names of two referees should be sent to the Establishments Officer, The University, College Gate, St Andrews, Fife, KY16 9AJ to arrive not later than 2nd July 1985 (6813)E

UNIVERSITY OF BERN
POST-DOCTORAL FELLOWSHIP
YEAST MOLECULAR GENETICS

This position opens on 1st October 1985 for a duration of two years with possible extension The holder of this position is expected to develop his own project in the frame of our group working on genetic recombination in S pombe Funding is from the Swiss National Science Foundation

Please send curriculum vitae, publication list and the names of two persons for references to Dr J Kohli, Institute of General Microbiology, Baltzerstr 4, CH-3012 Bern, Switzerland. (W1956)E

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL
POST-DOCTORAL FELLOWSHIP (MRC) IN HUMAN PHYSIOLOGY

The appointed person will join a small group under the leadership of Dr C T M Davies working on the physiology and biochemistry of elderly human muscles within the Department of Physiology and Pharmacology.

Post-graduates with appropriate experience of physiology interested in this Fellowship should write in the first instance to Professor P H Fentem, Department of Physiology and Pharmacology, Medical School, Queen's Medical Centre, Nottingham NG7 2UH, enclosing a curriculum vitae and the names of two referees (6895)E

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(University of London)

DEPARTMENT OF BIOCHEMISTRY AND CHEMISTRY

JUNIOR RESEARCH FELLOWSHIP

Applications are invited from Graduates or students obtaining a good honours degree this summer in Biochemistry or related subjects for a 3 year Junior Research Fellowship. The successful candidate will register for a higher degree in the University of London. The project concerns the Biochemistry of blood platelet activation. There will also be an opportunity to apply biochemical techniques to an investigation of abnormal platelet behaviour.

A curriculum vitae and the names of 2 academic referees should be sent to Dr K R Bruckdorfer, Department of Biochemistry and Chemistry, RFHSM, Rowland Hill Street, London NW3 2PF, as soon as possible

Further details are available on request. (6896)E

MERTON COLLEGE, OXFORD
JUNIOR RESEARCH FELLOWSHIPS AND SENIOR SCHOLARSHIPS 1986

The college proposes, if candidates of sufficient merit present themselves, to elect to two or three Junior Research Fellowships and to two or three Senior Scholarships in 1986. These awards are open to both men and women Candidates for Junior Research Fellowships must be under the age of 27 on 1 October 1986, candidates for Senior Scholarships must be under the age of 26, or, in the case of Oxford graduates, must not have exceeded 18 terms from the date of matriculation

Details of the awards and of the method of applying for them may be obtained from the Warden's secretary, Merton College, Oxford, OX1 4JD. The closing date for applications is Thursday 17 October 1985 (6842)E

POSTDOCTORAL FELLOWSHIP

available in immunology

Current emphasis is the study of the scrapie prion protein Techniques will include chemical and recombinant DNA synthesis of peptides, production of monoclonal antibodies, and protein immunochemistry.
Candidates must have a Ph D , M.D , or D V.M. degree and be a U S. citizen or a permanent resident
Send curriculum vitae and three letters of reference to.

Dr Stanley Prusiner,
Department of Neurology,
HSE 781,
University of California,
San Francisco,
California 94143.

The University of California is an Affirmative Action/Equal Opportunity Employer (NW1879)E

The John Hopkins University
Department of Anesthesiology and Critical Care Medicine

POST DOCTORAL FELLOWSHIP IN RESEARCH

Applications are invited for this position available immediately to study the molecular biology of human cytochrome P450. The applicant must be creative and highly motivated to carry out independent experimentation utilizing human cytochrome P450 under study.

M D or Ph D. required with 1–2 years experience in molecular biology.

Contact: Roy C. Levitt, M.D., The John Hopkins University, Department of Anesthesiology and Critical Care Medicine, Blalock 1410, Baltimore, Maryland 21205. Telephone (301) 955-7609. (NW1822)E

CANOLFAN ASTUDIAETHAU TIROEDD CRAS
COLEG PRIFYSGOL GOGLEDD CYMRU
UNIVERSITY COLLEGE OF NORTH WALES
CENTRE FOR ARID ZONE STUDIES
THE ROBERTSON FELLOWSHIP

Applications are invited for a Fellowship, initially for one year, commencing September/October, 1985 from scientists with an interest in General Agriculture and especially in Animal Husbandry of arid and semi-arid areas.

The successful applicant will contribute to the teaching of postgraduate and undergraduate courses and participate in the development of the Centre, including work on overseas contracts.

A basic salary in the region of £12,500 pa will be offered, but may be supplemented by other earnings.

Further details from: Professor R G Wyn Jones, Centre for Arid Zone Studies, University College of North Wales, Bangor, Gwynedd.

Applications (two copies), giving details of age, education and experience, together with the names and addresses of two referees, should be sent to the Personnel Office, University College of North Wales, Bangor, Gwynedd. LL57 2DG. (6860)E

STUDENTSHIPS

UWIST
University of Wales

APPLIED CHEMISTRY
RESEARCH STUDENTSHIPS IN BIO-INORGANIC CHEMISTRY
(Fixed-term 3 years)

To work in the field of chemical speciation modelling. Research areas include the speciation and bioavailability of trace metal ions in food stuffs, the interaction of pharmaceutical agents with metal ions and the chemical speciation of radioactive waste disposal systems.
Details from Professor David R. Williams, Department of Applied Chemistry, UWIST, PO Box 13, Cardiff CF1 3XF

RESEARCH ASSOCIATES
(fixed-term 2 years)

Chemical modelling of trace metal ions in natural waters, including the chemical speciation of radioelements in disposal systems.
Salary. Within Range 1A Research and Analogous Staff.
£7,520-£12,150 per annum
Requests (quoting Ref C72) for details and application form to Staffing Office, UWIST, PO Box 68, Cardiff CF1 3XA.
Closing Date: 25 July 1985.
(6837)F

ST MARY'S HOSPITAL MEDICAL SCHOOL
(University of London)
Norfolk Place, London W2 1PG
SERC CASE STUDENTSHIP

Applications are invited for a SERC Case Studentship in collaboration with Shell Research Limited (Dr D H Hutson) for research (leading to a PhD degree) into the effect of environmental conditions on the metabolism of chemicals by fish.

Applicants should have, or expect ot obtain, a first or second class honours degree in biochemistry, or chemistry, and have an interest in chemical and environmental toxicology.

Applications, including the names and addresses of two referees, should be sent to the Assistant Secretary (Personnel) at the above address by 3 July 1985. For further details of the studentship contact Dr P Millburn tel no: (01) 723-1252 ext 118 (6907)F

ROYAL HOLLOWAY AND BEDFORD COLLEGES
(University of London)
DEPARTMENT OF BIOCHEMISTRY
SERC/CASE STUDENTSHIP IN HERBICIDE BIOCHEMISTRY

Research studentship available in October 1985 to study the biochemical basis of herbicidal action of bleaching nitrodipheny-lethers, in collaboration with Shell Research Ltd. The project will involve the use of protein affinity labelling in purified plant membrane fractions. Candidates should expect to have a First or Upper Second Class honours degree in Biochemistry or a related subject.

Applications, including cv and the names of two referees, should be sent to Dr J R Bowyer, Department of Biochemistry, Royal Holloway and Bedford Colleges, Egham Hill, Egham, Surrey TW20 0EX (Tel: 0784 34455, ext: 259a) (6879)F

THE UNIVERSITY OF SHEFFIELD
RESEARCH STUDENTSHIPS IN PHYSICS AND GEOPHYSICS

leading to the degree of PhD, are available in the following areas.
Condensed Matter Physics
Metallic Glasses
Amorphous Semiconductors
Magnetism and Resonance Studies
Isotope Geophysics
Space Geophysics
Theoretical Physics

Applications are invited from graduates with first or upper second class degrees in Physics, Chemistry, Geology or Engineering
For further details please contact Professor I.G. Austin, Physics Department, Sheffield University, Sheffield S3 7RH. Telephone (0742) 78555 Ext 4351. Quote ref R300/G. (6906)F

UNIVERSITY OF DURHAM
SERC CASE RESEARCH STUDENTSHIP
The Mode of Action of a New Chemical Hybridising Agent.

Graduates in Plant Sciences, or other suitably qualified applicants, are invited to apply for the above studentship leading to the degree of PhD. The work will be carried out in collaboration with Shell Research Ltd, Sittingbourne, Kent.

The project will be centred upon a combined biochemical and biophysiological study of pollen development and behaviour in a variety of species, as modified by a new chemical hybridising agent. The work will involve autoradiography, microscopy (using newly developed epifluorescent techniques), amino acid and protein analysis

Enquiries are invited to Dr P Gates, Department of Botany, Science Laboratories, South Road, Durham, DH1 3LE (tel. 0385 64971), from whom further particulars may be obtained (6910)F

UNIVERSITY OF ABERDEEN
DEPARTMENT OF ENGINEERING
A MAJOR IMPACT IN ELECTRONICS

The University of Aberdeen, as part of a major new initiative in Electronics, is looking for research students for the following SERC CASE awards Commencing October 1985.

Knowledge Representation Using Massively Parallel Processors

in collaboration with the Admiralty Research Establishment (Portsmouth, UK) and Carnegie Mellon University (Pittsburg, USA)

A Reconfigurable, Fault Tolerant Network using Spread Spectrum Code Division Multiple Access Techniques

in collaboration with the Admiralty Research Establishment (Portsmouth, UK) and Netek Corporation (Chelmsford, Massachusetts, USA).

A methodology for the Design of Digital Systems

in collaboration with Fairchild Semiconductor (Reading, UK) and the Knowledge-Based VLSI Design Group at Xerox PARC (Palo Alto, USA)

High Level Applications Support for VLSI Systems

in collaboration with Fairchild Semiconductor (Reading, UK)

Control Protocols for a Packet Radio System

in collaboration with the Royal Signals & Radar Establishment (Malvern, UK)

Further particulars may be obtained from Professor C T Spracklen, Department of Engineering, University of Aberdeen, Natural Philosophy Building, King's College, Aberdeen. AB9 2UE (6908)F

UNIVERSITY OF READING
SERC-CASE STUDENTSHIP

Applications are invited for an SERC-CASE Studentship, in co-operation with IQ(Bio) Ltd of Cambridge, tenable for 3 years from October 1985 in the Department of Microbiology Applicants must have, or expect to receive this summer, a 1 or 2i honours degree in biochemistry or a closely related subject and have a particular interest in enzymology The successful applicant will investigate novel ultrasensitive enzyme-labelling systems for enzyme-linked immunosorbent assays (ELISA) and will register for a higher degree A minimum of 3 months will be spent at the IQ(Bio) Research Laboratories during the 3 years The value of the Studentship is £3,335 pa tax free (under review), plus University fees

Applications with full curriculum vitae including a telephone number and two academic referees should be sent as soon as possible to Dr L J Zatman, Department of Microbiology, University of Reading, London Road, Reading RG1 5AQ (6852)F

Southampton THE UNIVERSITY

INSTITUTE OF CRYOGENICS
CASE RESEARCH STUDENTSHIP

Applications are invited for an SERC/British Gas CASE studentship to study instabilities in cryogenic liquids using LDA, microthermometer and flow visualisation techniques

Apply to
Professor R.G. Scurlock
Institute of Cryogenics
University of Southampton
Southampton SO9 5NH
(6893)F

RESEARCH STUDENTSHIP

Applications are invited for an MRC research studentship, tenable in the MRC Cell Biophysics Unit at King's College London, for work in one of the following areas: Muscle structure on cross-bridge kinetics; cellular developmental neurobiology; cell movement; structure of the cyto skeleton

Applicants should send a copy of their curriculum vitae, and ask two academic referees each to forward an assessment, as soon as possible to Mr D M Drummie, King's College London, 26-29 Drury Lane, London WC2B 5RL (6890)F

THE UNIVERSITY OF MANCHESTER

DEPARTMENT OF BOTANY

SERC-CASE STUDENTSHIP NITRATE REDUCTION IN PLASTIDS OF HIGHER PLANT ROOTS

Applications are invited from graduates and final-year undergraduates for a 3 year studentship to be supervised by Dr M J Emes (Department of Botany, University of Manchester) and Dr D P Hucklesby (Long Ashton Research Station, Bristol) The aim of the project is to identify and characterise the natural electron donor for nitrite reductase in roots, and the person appointed will receive training in the techniques of protein purification, immunobiochemistry, and organelle isolation Applicants should have, or expect to obtain, a First or Upper Second class Honours degree in Biochemistry, Biology or Botany and have an interest in plant metabolism and enzymology

Applications containing a curriculum vitae and the names and addresses of two referees should be sent as soon as possible to Dr M J Emes, Department of Botany, The University, Manchester M13 9PL (6838)F

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF MICROBIOLOGY

Applications are invited for a

POSTGRADUATE RESEARCH STUDENTSHIP

The research project will involve investigation of the molecular genetic and physiological basis of virulence in pathogenic Neisseria.

The studentship is funded by MRC and is for three years, starting on 1st October, 1985 Applicants should have a First or Upper Second Class Degree in Microbiology, Biochemistry, Genetics or a related discipline.

Informal enquiries may be made to Dr J R Saunders, Tel: 051-709 6022 Ext: 3159.

Applications together with the names of two referees should be received as soon as possible by The Registrar, The University, PO Box 147 Liverpool, L69 3BX

Quote Ref. RV/117/N. (6867)F

ROBERT GORDON'S INSTITUTE OF TECHNOLOGY, ABERDEEN

SCHOOL OF PHARMACY RESEARCH STUDENTSHIP

Applicants with 1st or 2nd Class Honours Degree in Pharmacy or Pharmacology to study the mechanisms of action of possible antithrombotic drugs

Project funded by the British Technology Group and supervised by Dr G M Smith

Application forms from: The Personnel Department, Robert Gordon's Institute of Technology, Schoolhill, Aberdeen, AB9 1FR (6866)F

UNIVERSITY OF LEICESTER

Department of Genetics

Applications are invited for a SERC research studentship in Genetics tenable for 3 years from October 1985. The award is 'earmarked' by SERC for research in the genetic analysis of Drosophila behaviour Applicants should have or expect to have a degree (1st class or 2/1) in a Biological subject and have an interest in molecular, genetic or evolutionary aspects of behaviour.

The Department is well equipped for research in genetics and has excellent facilities for molecular biology

Enquiries and applications may be made to Dr C P Kyriacou, Department of Genetics, Adrian Building, University of Leicester, Leicester LE1 7RH (6811)F

UNIVERSITY OF LEICESTER

SCHOOL OF BIOLOGICAL SCIENCES

(BOTANY DEPARTMENT)

SERC — CASE STUDENTSHIP (ICI Corporate Biosciences Group)

An SERC-CASE Studentship in collaboration with Dr W Schuch of the ICI Corporate Biosciences Group is available to work on a project concerned with the molecular biology of phytochtome action in light-grown plants, with particular respect to the control of growth and lignification in crop plants experiencing mutual shading. The work will involve the use of cDNA probes to estimate PAL mRNA levels and to measure specific transcription rates.

Applicants having, or expecting to achieve, at least an Upper Second Class Honours Degree in an appropriate subject should submit a curriculum vitae, with the names of two referees, as soon as possible to Professor H Smith, Department of Botany, University of Leicester, University Road, Leicester. (6863)F

UNIVERSITY OF BRISTOL

DEPARTMENT OF BOTANY

Applications are invited for an

SERC RESEARCH STUDENTSHIP

commencing October 1985 to work in one of the following areas of plant science: physiology/biochemistry, molecular genetics, ultastucture, mycology or phycology. Candidates should possess or expect to obtain at least an upper second class honours degree in a Biological Science or related subject.

Applications, which should include a cv and the names of two referees should be sent as soon as possible to Professor A E Walsby, Department of Botany, University of Bristol, BS8 1UG. (6897)F

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF BIOCHEMISTRY

SERC STUDENTSHIP

October 1985

Applications are invited for a studentship expected to lead to a Ph.D. degree for research on inherited biochemical lesions resulting in ketoacidosis in humans. The work will involve cultured skin fibroblasts from affected and unaffected individuals.

Applicants will need a first or upper second class honours degree in Biochemistry or a closely related subject

Applications including curriculum vitae and names of two academic referees to Dr B. Middleton, Department of Biochemistry, University of Nottingham Medical School, Queen's Medical Centre, Nottingham NG7 2UH (6877)F

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF PHARMACOLOGY

MRC RESEARCH STUDENTSHIP

Applications are invited for MPhil/PhD work on electrophysiological investigations (particularly single ion channel recording) in peripheral ganglion cells and/or CNS neurons

Send CV and names of two referees to Professor D Colquhoun, Dept of Pharmacology, University College London, Gower Street, London WC1E 6BT. (6882)F

UNIVERSITY OF OXFORD

Dyson Perrins Laboratory (Organic Chemistry)

SERC POSTDOCTORAL RESEARCH ASSISTANTSHIPS

Applications are invited for postdoctoral research assistantships to work on the Isolation, Characterisation and Modification of Beta-Lactam Biosynthesis Enzymes from Cephalosporium and Streptomyces One post will involve enzyme isolation, kinetics, enzymatic synthesis of novel Beta-lactam antibiotics etc and the other one will involve the application of Recombinant DNA techniques. Candidates with experience of enzymology, molecular biology or bioorganic chemistry will be preferred The appointments are on the RA1A scale with starting salary up to £8,920 pa plus USS according to age and experience and would be initially for one year from October 1985 with the possibility of extension

Applications with curriculum vitae and the names and addresses of two referees should be sent as soon as possible to Prof J E Baldwin, Dyson Perrins Laboratory, South Parks Road, Oxford, OX1 3QY (6848)P

CITY OF LONDON POLYTECHNIC

Post-Doctoral Research Assistantship in Dendrochronology

Applications are invited for an SERC-funded post-doctoral Research Assistantship to be held jointly by the City of London Polytechnic and The Queen's University, Belfast. The successful applicant, who will be required to work for two years on the dating of buildings in north-west France by dendrochronology, will be based largely in London, but must expect to spend some time in Belfast and significant periods each year in the field in France. Previous experience of dendrochronology work is highly desirable Starting salary: £8,586 pa including London Allowance (pay review pending)

Further information and an application form may be obtained from Professor G I Meirion-Jones, Department of Geography, City of London Polytechnic, Old Castle Street, London E1 7NT, tel. 01-283 1030 ext 464. (6880)P

UNIVERSITY OF SOUTHAMPTON

Clinical Pharmacology/ Medicine 1

SERC (CASE) STUDENTSHIPS

Applications are invited from good honours graduates in pharmacology, biochemistry or physiology for the following SERC (CASE) studentships to study:

1. The biochemical pharmacology of dispersed human skin mast cells (in collaboration with Roussel Laboratories Ltd)

2 The development of bronchial hyper-reactivity in the guinea-pig (in collaboration with Roussel Laboratories Ltd)

3 The oxidative metabolism of arachidonic acid in human and primate mast cells (in collaboration with Fisons Pharmaceuticals PLC).

The studentships are available for 3 years from October 1st 1985 and the successful applicants are expected to register for a higher degree. Further information and applications, including curriculum vitae and the names of two referees to: Dr M K Church, Clinical Pharmacology, Southampton General Hospital, Southampton, SO9 4XY. Telephone 0703-777222 ext. 4312. Applications close June 30th 1985. Please quote reference No AJS/85/40/NA. (6836)F

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF GENETICS

NERC RESEARCH STUDENTSHIP

Two studentships are available from October 1985 to work on the following projects

Dr A B Tomsett / Dr D A Thurman: Genetics of heavy metal tolerance in Aspergillus nidulans. This project aims to isolate resistant mutants from laboratory strains, to determine the genetic and physiological basis of these tolerances and to compare them with other fungal species isolated from metal-contaminated environments.

Prof D A Ritchie/Dr P Strike: The distribution of heavy metal detoxification genes in aquatic bacteria. This project aims to use previously cloned mercury and tellurium resistance genes as probes to investigate the presence of similar genes in a wide variety of bacteria from habitats around the River Mersey and to identify new genetic elements associated with these resistances Contact Dr P Strike for further details (051 709 6022 ext 3113).

Applicants should have, or expect to obtain, a 2.1 or 1st class Honours degree in Genetics, Microbiology, Biochemistry or Molecular Biology. Applications, including a CV and the names and addresses of two referees, should be sent as soon as possible to The Registrar, The University, PO Box 147, Liverpool, L69 3BX

Quote Ref: RV/114/N. (6845)F

UNIVERSITY COLLEGE LONDON

MRC NEUROIMMUNOLOGY PROGRAMME and ICRF TUMOUR IMMUNOLOGY UNIT

Department of Zoology

TWO RESEARCH STUDENSHIPS

Applications are invited for the above studentships to study

a) the molecular basis of cell-cell interactions in the development of the peripheral nervous system using monoclonal antibodies and cell culture. The MRC group comprises approx. 15 scientists and research students working together in the field of developmental neurobiology.

b) cell surface molecules involved in the activities of B lymphocytes using monoclonal antibody and molecular techniques. The ICRF group comprises approx 25 scientists and research students working in a wide range of immunological areas.

Candidates should hold or expect to receive a first or upper second class honours degree.

Applications should include a C.V. and the names of at least two academic referees and be sent to:

a) Dr A. W. Mudge and
b) Dr M. J. H. Ratcliffe
Dept. of Zoology
University College London
Gower Street
London WC1E 6BT

(6871)F

UNIVERSITY OF WALES COLLEGE OF MEDICINE

DEPARTMENT OF PATHOLOGY

PhD STUDENTSHIP (CRC FUNDED)

Applications are invited from graduates holding or expecting to obtain a 2(i) degree or higher in biochemistry, molecular biology, or related subjects, to work for 3 years on the molecular basis of thyroid cancer, using both an existing experimental model and human thyroid tumours.

The successful candidate will join an established group funded largely by the Cancer Research Campaign, and will gain experience in a wide range of recombinant DNA techniques, including gene transfer.

This post is available from September 1st. Further information can be obtained from Drs D or V Wynford-Thomas (Tel No. 0222/ 755944 Ext 3440)

Applications, in the form of a curriculum vitae with the names and addresses of two referees, should be submitted to the Registrar and Secretary, University of Wales College of Medicine, Heath Park, Cardiff, CF4 4XN (quoting Ref No P1/47) within two weeks of the appearance of this advertisement (6898)F

Teesside Polytechnic

Department of Chemistry

Department of Chemical Engineering

(NORTH EAST BIOTECHNOLOGY CENTRE)

SERC CASE STUDENTSHIP

A SERC Case Studentship is available to commence in September 1985. The overall aim of the project is the design of an industrial process for the selective hydrolysis of natural plant lipids using lipase. The award is in collaboration with *Croda Universal Ltd.* who will enhance the grant payable to the successful applicant.

Candidates should hold, or expect to gain a good Honours degree in Chemical/Biochemical Engineering or Biotechnology.

For further details and application forms please write to:

Graham Street, NEBC, Department of Chemical Engineering Teesside Polytechnic, Borough Road, Middlesbrough, Cleveland. TS1 3BA. Telephone: (0642) 218121 ext. 4284 within two weeks of the appearance of this advertisement. (6850)F

LIVERPOOL POLYTECHNIC

School of Pharmacy

CASE STUDENTSHIP

STRUCTURE-ACTIVITY STUDIES ON ALPHA-BLOCKING AGENTS

Applications are invited for a CASE studentship, in collaboration with Reckitt and Colman Pharmaceutical Division, for research into the relationships between molecular structure and pharmacological activity in a series of alpha-adrenoceptor antogonists. Applicants should hold, or expect to gain this year, at least an upper second class honours degree in an appropriate discipline

Please write giving full details to

Dr J. C. Dearden, School of Pharmacy, Liverpool Polytechnic, Byrom Street, LIVERPOOL L3 3AF (Tel 051 207 3581 Ext. 2066).

Liverpool Polytechnic is an Equal Opportunity Employer and welcomes applications irrespective of race, sex, marital status or disability (6876)F

UMIST

NEUROBIOLOGY/ NEUROCHEMISTRY

Applications are invited for a PhD CASE Studentship (sponsors SERC and Dow Chemical Co) to work on the action of neuronal 5 hydroxytryptamine in the insect nervous system The project will involve electrophysiological techniques in the locust (in particular intracellular recording) neuroanatomical techniques, pharmacology and possibly biochemical analysis. Applicants must be of at least upper second class quality.

For further details write to Dr N M Tyrer, Department of Biochemistry and Applied Molecular Biology, UMIST, PO Box 88, Manchester M6O 1QD. Please quote reference BIO/S13. (6905)F

Southampton THE UNIVERSITY

Department of Chemistry

Applications are invited from students holding, or expecting to hold, a good Honours Degree in Chemistry for a

STUDENTSHIP

funded by ICI Organics Division. The project involves the electrosynthesis of reactive metal alkyls

Applications should be sent to:

Dr Derek Pletcher, Department of Chemistry, The University, Southampton SO9 5NH

COURSES & CONFERENCES

ADVANCED COURSE IN FLOW CYTOMETRY: ANALYSIS AND FLUORESCENCE ACTIVATED CELL SORTING

Paris, September 9–14, 1985

Sponsored by. The Cancer Research Association (ARC) - Jacques Crozemarie, President, and the "Centre Technique pour le soutien de la Recherche sur le Cancer des Laboratoires et Formations du Centre National pour la Recherche Scientifique" (C N R S.)

A Course in Flow Cytometry will be offered with special emphasis on cell biology Themes will include Multiparameter cell sorting, cell lineage studies, tumor cells characterization, gene amplification selection, cloning of genes by transfection, somatic cell genetics, hybridoma variant selection, liposome endocytosis, cell cycle analysis, Brd U and cytokinetic studies, mathematical modeling of the cell cycle, computer system for multiparameter data analysis, cytochemistry and new fluorochromes, karyotype analysis, pumped dye lasers, emission anisotropy

The Course will consist of lectures, laboratory demonstrations and problem solving sessions

Course Directors. Harry Crissman (Los Alamos National Laboratories), Claude Rosenfeld (INSERM, Villejuif, France)

Organizers: L A. Herzenberg (Standford University, USA), P Le Bouteiller (Centre d'immunologie de Marseille-Luminy, France), Z. Mishal (C N.R.S., Vilejuif, France), M. Monsigny (Centre de biophysique moléculaire, Orleans, France), J.L. Roti-Roti (Washington University of St. Louis, USA)

Z Darzienkiewicz, P Dean, M Goldberg, J. Gray, P Horan, C Julien, M Loken, H S Micklem, K Muirhead, D.R. Parks, A Truneh

Course tuition $500 (5 000 FF) includes laboratory fees, manual, coffee breaks, lunches and an optional Flow Cytometry Certificate

Send C.V and tuition deposit $50 (500 FF) to the local Course Director (max 50 persons)

Dr Claude Rosenfeld,
INSERM Unite 253,
Groupe Hospitalier Paul Brousse,
16 bis avenue Paul Vaillant Couturier,
94804 Villejuif, France

Application deadline June 30 1985, priority given to early applicants. **(W1919)C**

KINGSTON POLYTECHNIC — PART-TIME MSc

EARTH SCIENCE and the ENVIRONMENT
7th INTAKE. JANUARY 1986

Applications are welcomed from graduates with Honours degrees or equivalent qualifications in Geology, Geography or related subject areas

For further information contact Dr R T J Moody,
School of Geological Sciences, Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. Tel: 01-549 1366.

PROPOSALS

CALL FOR PROPOSALS TO HOUSE THE WORLD DATA CENTRE FOR COLLECTIONS OF MICROORGANISMS OF THE WORLD FEDERATION FOR CULTURE COLLECTIONS

Because of the impending retirement of the Director, the World Data Centre (WDC) must be relocated and offers are sought from institutions willing to house and develop this important information centre The WDC is part of the World Federation of Culture Collections (WFCC) and is responsible for the collection, storage and distribution of information about culture collections internationally. It forms an essential resource for the support and development of microbiology in research, education and industry

Detailed information on requirements is available in the Request for Proposals document available from the WFCC's Steering Committee for the WDC or The President members of the WFCC. Applicants are required to provide a detailed specification of mechanisms for implementation of the databank, qualifications, resources and policy. This, or letters of intent, must be sent to the President WFCC by August 1st. Applicants will be assessed by the Steering Committee and recommendations made to the Executive Board of WFCC, which will make the final decision. Relocation must be completed by July 1986 and every assistance will be given to the successful applicant to complete a smooth transition of this important centre.

Steering Committee contacts· Dr M Krichevsky, Microbial Systematics Section, National Institute of Dental Research, National Institutes of Health, Building 10, Trailer A, Bethesda, Maryland 20205, USA; Dr R Hill, National Collection of Type Cultures, Central Public Health Laboratory, 61 Colindale Avenue, London NW9 5HT; Dr R E Stevenson, American Type Culture Collection (ATCC), 12301 Parklawn Drive, Rockville, Maryland 20852, USA and Dr H Sugaware, Kenkyuu-jouhoushitu, Riken, 2-1 Hirosawa, Wako-shi, Saitama 351, Japan.

President WFCC: Mrs B Kirsop, National Collection of Yeast Cultures, AFRC Food Research Institute, Colney Lane, Norwich NR4 7UA. (6847)X

LECTURES

SECOND AND FINAL ANNOUNCEMENT

Lunteren Lectures on Molecular Genetics
International Meeting on

'GENETIC ENGINEERING OF PLANT CELL FOR AGRICULTURE AND PRODUCTION'

BIO/TECHNOLOGY'S PREMIER CONFERENCE

Whether you're an R&D Project nager, VP of Research, a Senior entist, a Process Engineer, Depart- nt Chairman or an Academic Re- rcher—this is *one* conference you 't afford to miss.

or our first conference, we've planned e days of free-wheeling discussions researchers and research managers set the pace in biotechnology. You'll n about up-to-the-minute develop- nts in the world of molecular biology. you'll get a jump on the ideas and nniques that will guide biotechnology ough the '80s and '90s. articipation is limited. So don't delay. gister now to guarantee your place.

cation: Clarion Hotel, 1500 Canal St., w Orleans, LA 70112.

om Reservations: Rooms can be erved directly with the hotel by calling 00-362-6000 or 1-504-522-4500. Be certain to reserve early and mention your participation in the BIO/TECHNOLOGY CONFERENCE to take advantage of our special convention rates. **Singles:** $53, $60, $68, $75, $80. **Doubles/Twins:** $63, $70, $78, $85, $90.

Poster Sessions: Scientists are welcome to submit abstracts of work with commercial applications for consideration. Mail abstracts to Research Editor, BIO/TECHNOLOGY, 65 Bleecker Street, New York, NY 10012.

Exhibits: An exhibit of the latest in fermentation and separation equipment, instrumentation, and other products related to biotechnology will be on display.

To Register: Return the form with your check, credit card authorization or an authorized purchase order.

harles Arntzen, Associate Director of Central esearch and Development, E.I. Du Pont de emours and Co.

ANUARY 21—MORNING

ommercial Production Processes

peakers:
alcolm Lilly, Professor of Chemistry and iochemical Engineering, University College, ondon
obert Herschberg, Department of Process evelopment, Genentech
ukio Sugino, Director, Biotechnology Labs, akeda Chemical, Japan
phraim Katchalski-Katzir, Professor of iophysics and Biotechnology, Tel Aviv niversity, Israel

ANUARY 21—AFTERNOON

eminar in Scale Up

alcolm Lilly, Co-Chairman
obert Herschberg, Co-Chairman
arry Buckland, Director, Computerized Pilot lant, Merck, Sharp, & Dohme

Stanley Tarnowski, Research Section Chief, Dept. of Bioseparations, Hoffmann-La Roche

Seminar in Fermentation

Yukio Sugino, Chairman
Arnold Demain, Director of Laboratory of Fermentation and Microbiology, MIT
Behzad Khosrovi, Senior Director, Process and Product Development, Cetus Corp.
William Tolbert, Research Fellow, Monsanto

Seminar in Immobilization & Biocatalysis

Ephraim Katchalski-Katzir, Chairman
Allen Laskin, Industrial Consultant, Chairman, BIO/TECHNOLOGY Scientific Board
Gary Calton, President, Purification Engineering, Inc.

JANUARY 22—MORNING

Innovations in Pharmaceuticals & Immunology

Speakers:
Bernard Moss, National Institutes of Health
Emil Thomas Kaiser, Haggerty Professor, Rockefeller University
George Poste, Vice President and Director of R&D, Smith Kline & French

JANUARY 22—AFTERNOON

Seminar in Vaccine Development

Bernard Moss, Chairman
Pablo Valenzuela, Vice President and Director of Research, Chiron Corp.
Mark Greene, Professor, Dept. of Pathology, Harvard Medical School

Seminar in Peptide Design

Emil Thomas Kaiser, Chairman
Gregory Winter, MRC, Mill Hill, Cambridge, U.K.
Gregory Petsko, Professor, Dept. of Chemistry, MIT

Seminar in Drug Delivery

George Poste, Chairman
Joseph Robinson, Professor of Pharmacy, Univ. of Wisconsin
Colin Gardner, Director of Analytical and Biological Research, Inter X, a subsidiary of Merck & Company

Look at the *NEW* Automatic Injector ACT-100 . . .

. . . because the Pharmacia Automatic Injector ACT-100 is a versatile, microprocessor controlled instrument designed to free you from the chore of repeated sample injection while your chromatographic separations run automatically.

The Automatic Injector ACT-100 is the state of the art in high performance biocompatible chromatography equipment designed specifically for the separation of biomolecules. Unlike any other injector, the Automatic Injector ACT-100 was designed,

from the beginning, to meet the demands of high performance separations of complex biomolecules. All wetted surfaces in the ACT-100 are of titanium and fluoroplastic. So the ACT-100 and FPLC System can combine to form a totally biocompatible system.

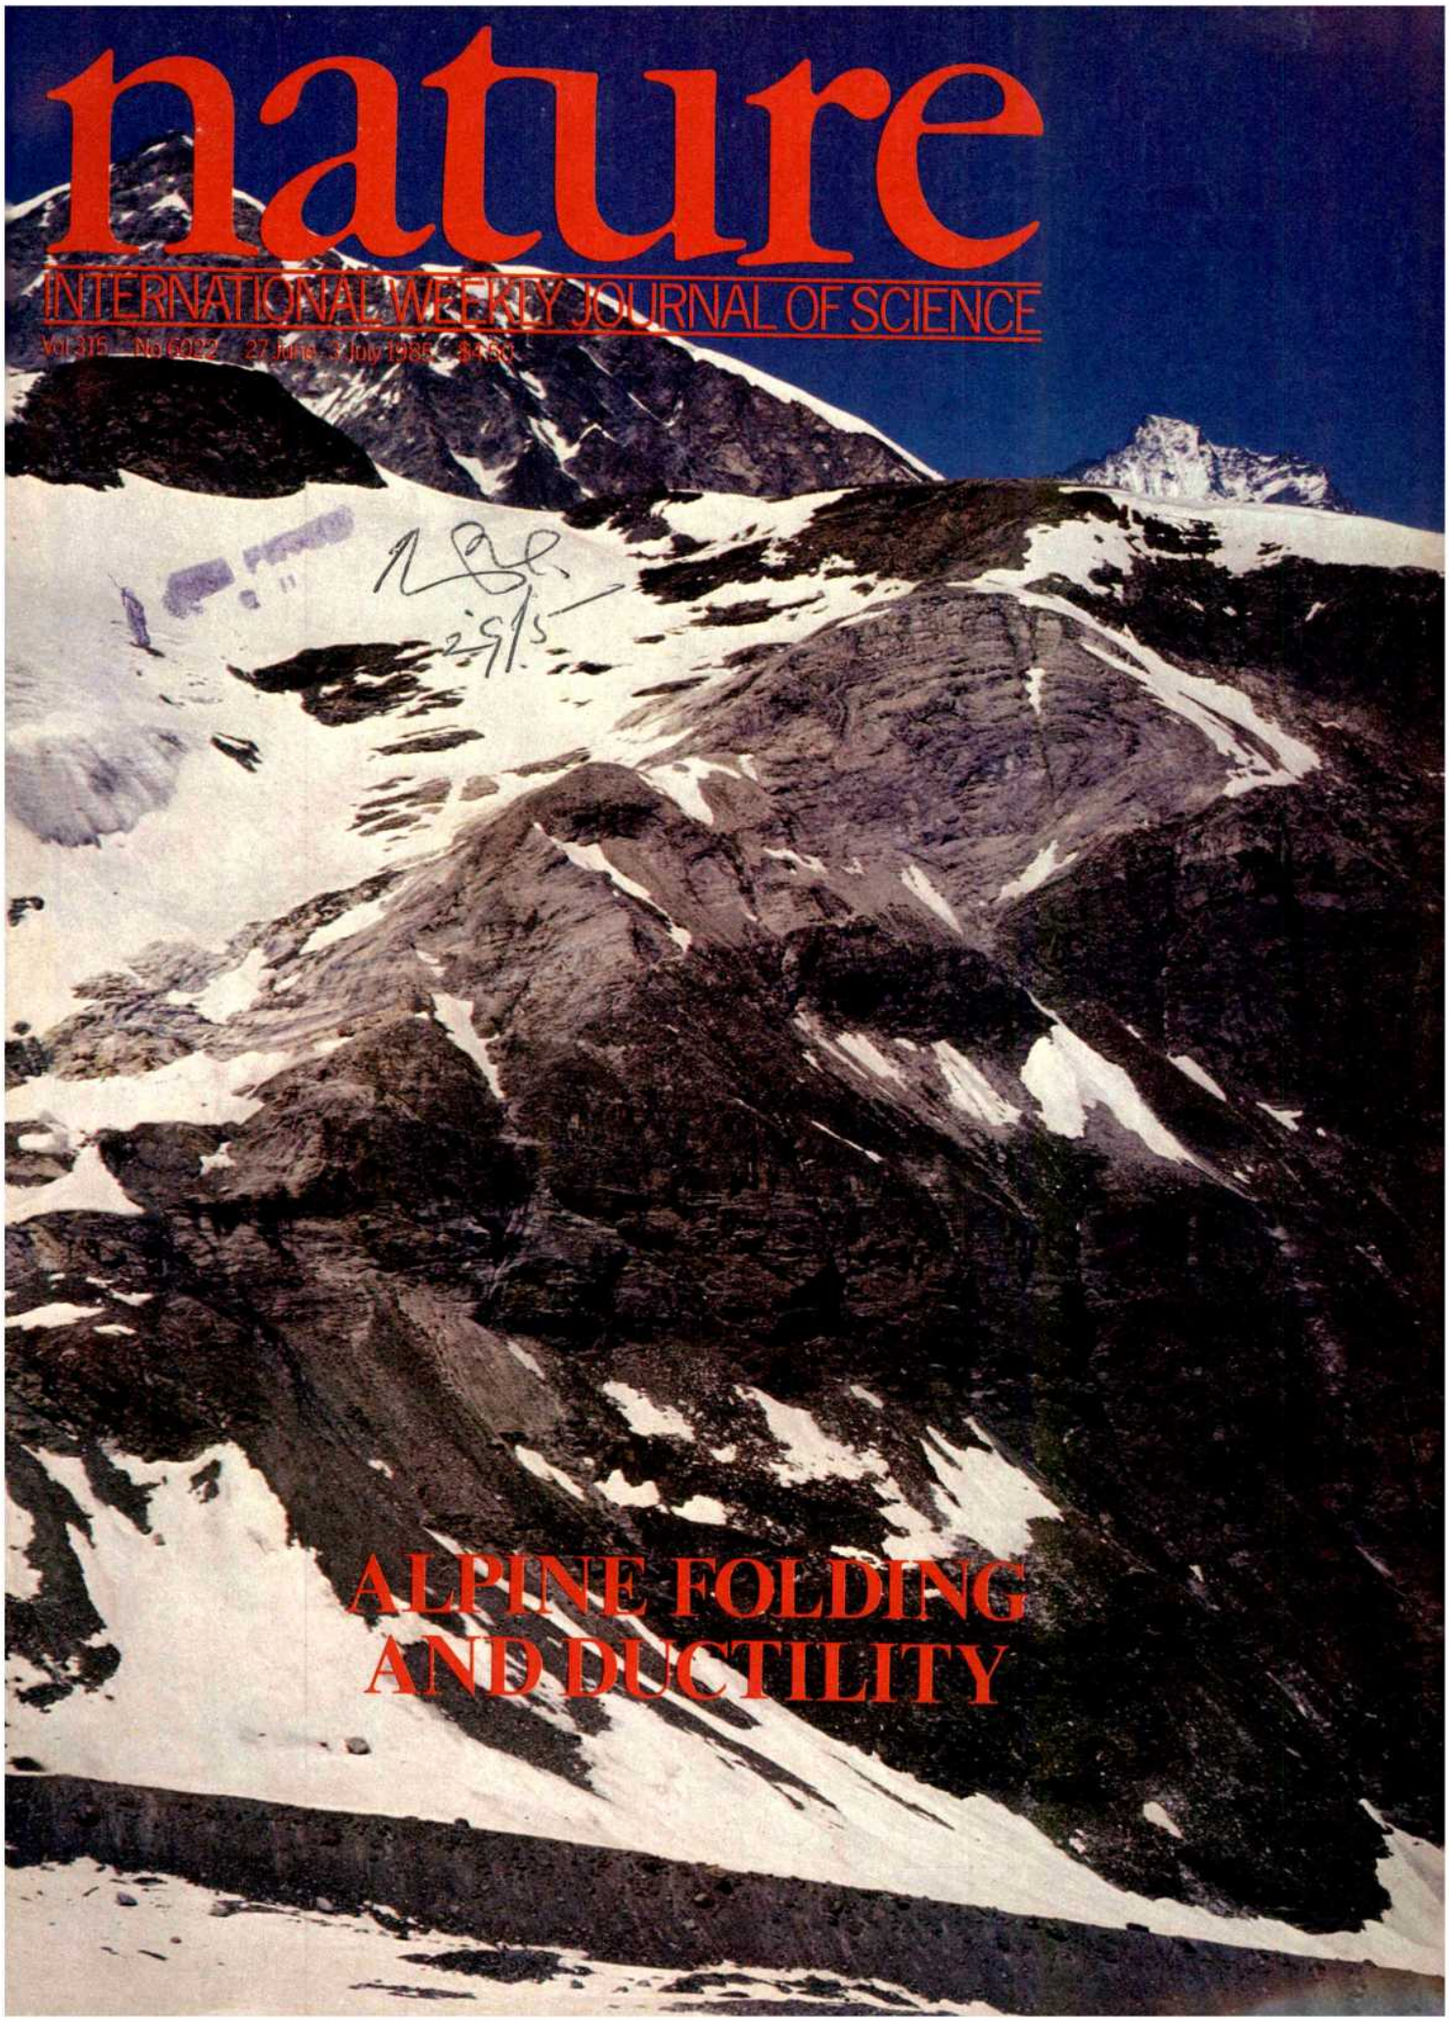
And, like the FPLC System, the ACT-100 is completely modular. Depending on your existing equipment, you can select the exact system configuration to give you a completely automated, biocompatible chromatography station.

. . . for automated biocompatible chromatography.

Complete automation with the Pharmacia Automatic Injector ACT-100 means

- Automatic analysis of up to 95 consecutive samples
- Accurate and reproducible results
- Unattended overnight runs, even with multi-dimensional systems
- Minimal operator time

The Pharmacia FPLC System and the Automatic Injector ACT-100 bring the full benefits of the latest technology to your standard methods. Together, they form the perfect biocompatible, high performance liquid chromatography system for the separation of labile biomolecules.



FPLC from Pharmacia goes beyond HPLC with biocompatibility.

The new LKB Quality Chemicals Catalogue

Hot off the presses is a new 76-page, full-color catalogue—the LKB Quality Chemicals Catalogue. This latest edition packs comprehensive, up-to-date information on all the reagents, buffers, separation media and other supplies available from LKB. It also provides more information about each product, more applications and complete information on several new products such as preparative-scale chromatography columns, new HPLC columns, and amino acid analysis buffers and reagents.

If your lab does electrophoresis, electrofocusing, chromatography, HPLC, luminescence, liquid scintillation counting, amino acid analysis or cellular biology, you can't afford to be without it. Offering complete descriptions of the nearly 400 fine chemicals and consumables in our range, it's your mail-order reference to the single-source supplier. Ask for your free copy today.

ANNOUNCING A NEW GENERATION OF AUTOMATED PEPTIDE SYNTHESISERS

THE REVOLUTIONARY NEW CHEMISTRY AND DESIGN OF THE CRB PEPSYNTHESISER II HERALDS A NEW ERA IN PEPTIDE SYNTHESIS.

- ▷ Fast, simple coupling of amino acids with new, stable off-the-shelf 'Pepsyn' Fmoc/ active esters requiring no pre-activation.
- ▷ Exceptionally mild reaction conditions, avoiding damaging repetitive acid treatments, lead to higher yields and higher product purity.
- ▷ Avoids the hazardous and frequently destructive final liquid hydrogen fluoride treatment.
- ▷ Unprecedented coupling efficiency results from the combined use of polar polyamide resins (traditionally polystyrene) and a freely permeating polar solvent providing complete compatibility between reaction medium and the growing peptide chain.
- ▷ Continuous monitoring of reaction progress and the option of simultaneous synthesis of two or more peptides is achieved by use of novel kieselguhr supported polyamide resins specifically designed to permit continuous flow of solvent through the reaction medium.
- ▷ Coupling, deprotection and washing automatically performed under computer control using simple programs in everyday language.

FPLC from
goes beyond HPLC
The pace of today's biological research allows no compromise in the performance of your separation tools. No compromise in performance means instruments and separation media designed and optimized specifically for biomolecules. The Pharmacia FPLC System stands alone as the original high performance liquid chromatography system designed for the special needs for such applications as:
• Enzyme purification
• Peptide mapping
• Analytical protein separations
• Purification of biologically active peptides
• Separation of polynucleotides
FPLC is a unique approach, designed to eliminate the incompatibilities of traditional HPLC technology. For the last 20 years, traditional HPLC pump design, high pressure columns and stainless steel wetted surfaces were developed to solve problems different from the ones you have today.
Why "make-do" with compromise using old HPLC technology when FPLC has proven itself with such difficult samples as monoclonal antibodies, restriction enzymes, blood, urine and viral proteins?
After 25 years of experience in developing basic separation methods like gel filtration, affinity chromatography and chromatofocusing, we at Pharmacia can tell you that FPLC incorporates some of the most significant discoveries in separation chemistry since the introduction of Sephadex®.
FPLC respects the origins of the biomolecule and achieves unprecedented speed, resolution and recovery.

Hot on delivery...

...cold on arrival

When you order molecular biologicals from Pharmacia you'll find we're pretty hot on delivery.

We'll dispatch your order as soon as we get it, packing it carefully in wet or dry ice.

Now our enzymes are supplied in screw cap mini vials with new waterproof labels, and will easily fit into your centrifuge tubes and freezer trays.

At Pharmacia Molecular Biology Division that's all part of the service. We realize that the success of an experiment depends on the quality of the products used and the speed at which you get them. With us you'll find that the only thing kept on ice is your product – not your experiment.

Contact us today and we'll send you our free catalog with details of over 800 molecular biologicals.

Pharmacia... your partner in molecular biology.

- Quasi-crystals
- Nuclearites?

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible

Review articles should be accessible to the whole readership Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable)

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding The text should not exceed 3,000 words and six displayed items (figures plus tables) The article should include an italic heading of about 50 words

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in ***Nature.*** The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted

Manuscripts may be submitted either to London or Washington) Manuscripts should be typed (double spacing) on one side of the paper only Four copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length Reference lists, figure legends, etc, should be on seperate sheets, all of which should be numbered Abbreviations, symbols, units, etc, should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts, in the text and should be abbreviated according to the *World List of Scientific Periodicals,* fourth edition (Butterworth 1963-65) The first and last page numbers of each reference should be cited Reference to books should clearly indicate the publisher and the date and place of publication Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text

Each piece of artwork should be clearly marked with the author's name and the figure number Original artwork should be unlettered Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

YOUR REGISTRATION FEE COULD BE TAX DEDUCTIBLE

CONFERENCE DINNER
Our gala Conference dinner will be held Tuesday, October 8, in the historic, glass-domed Garden Court. To insure seating, please include your dinner ticket requirements and payment of $29.50 per person with your registration.

EXHIBITS
A major exhibition of scientific products and services will be held in conjunction with the Conference.

PROGRAM SCHEDULE*

DAY 1: MONDAY, OCTOBER 7

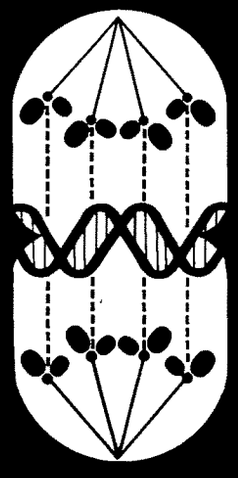
SYSTEMS

Speakers	*Topics*
F. Bloom (Research Institute of Scripps Clinic)	Vertebrate neural systems
J. Gerhart (U. of California at Berkeley)	Early development—Xenopus
C. Nüsslein-Volhard (Tübingen)	Early development—*Drosophila*
C. Goodman (Stanford)	Development of invertebrate neural systems
H.R. Horvitz (MIT)	Caenorhabditis

DAY 2: TUESDAY, OCTOBER 8

CELLS

Speakers	*Topics*
M. Davis (Stanford)	T-cell receptors
U. Storb (U. of Washington at Seattle)	B cells
J.M. Bishop (U. of California at San Francisco)	Oncogenes
M. Ptashne (Harvard)	Regulatory proteins
I. Herskowitz (U. of California at San Francisco)	Yeast development
E. Jaworski Monsanto	Plant transformation



DAY 3: WEDNESDAY, OCTOBER 9

GENES

Speakers	*Topics*
R. Palmiter (U. of Washington at Seattle)	Transgenic mice
D. Hogness (Stanford)	*Drosophila* homoeotic genes
W. McGinnis (Yale)	Mammalian homoeotic genes
T. Friedmann (U. of California at San Diego	Human therapy

*Additional speakers will also appear on the program.

SAVE $50 IF YOU REGISTER BEFORE JULY 31!

UPDATE IN MOLECULAR BIOLOGY 1985

Genes and Systems in Development

You are invited to join a select group of participants and some of the world's foremost speakers at NATURE's fifth international conference.

Presented in conjunction with the University of California at San Francisco.

OCTOBER 7, 8, 9, 1985–SHERATON-PALACE HOTEL SAN FRANCISCO, CALIFORNIA

The 1985 conference presented by NATURE, the international weekly journal of science, in association with the University of California at San Francisco will address what is perhaps the central unanswered question of biology today: How is the process of development directed by genes?

For three days, you will meet and listen to preeminent scientists, physicians and biotechnologists describe their research and first-hand involvement in experimental approaches involving the application of molecular biology to systems and organisms. Topics will include the diagnosis and therapy of genetic defects, homoeotic genes, yeast development, development of the immune system—including T-cell receptors—and the use of new biological materials in medicine and industry. Roundtable discussions will be held each afternoon to give delegates ample opportunity to mix with and question the speakers. Participants will have an opportunity to take part in detailed discussions and present their own ideas. Poster presentations are also being invited.

WHO SHOULD ATTEND

Senior Level Scientists, Medical Research Scientists, Biotechnologists, Scientific Policy Makers, R & D Scientists, Departmental Chairpeople.

TO REGISTER FOR THE CONFERENCE

Return the form with your check, credit card authorization, or an authorized purchase order.
Full 3-day registration fee: $375.00
Pay only $325.00 if you register before July 31.

LOCATION

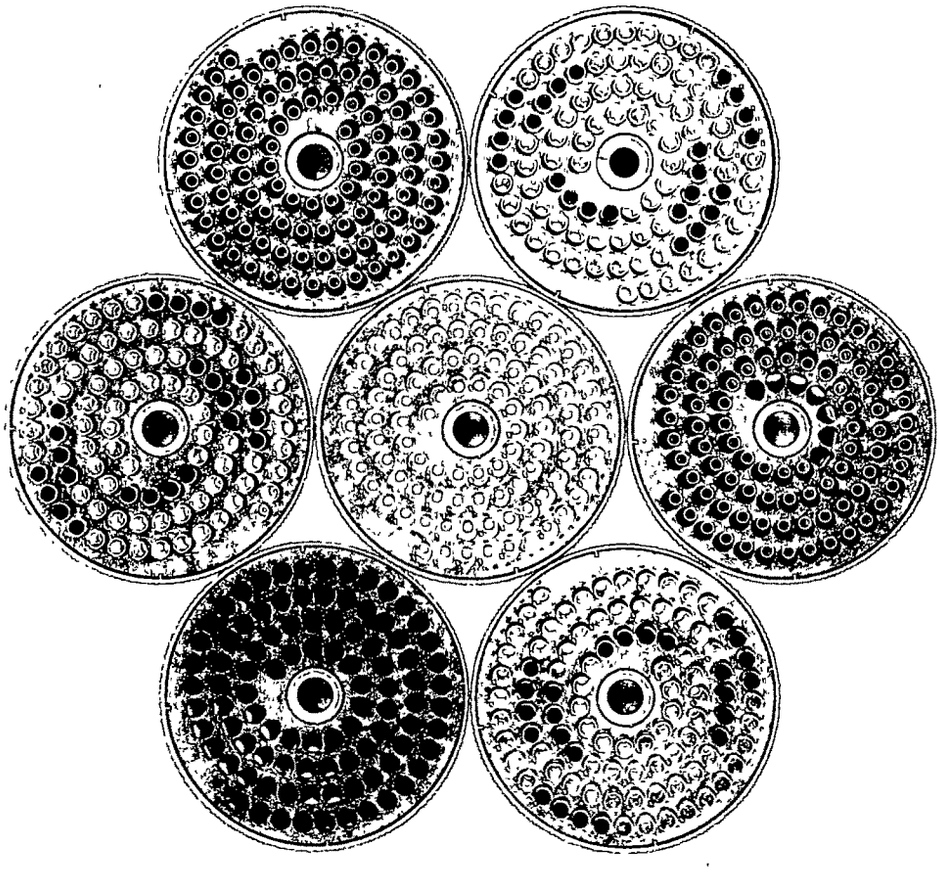
The Sheraton-Palace Hotel located at 639 Market Street is convenient to the business and financial districts as well as downtown's most stylish shops and finest restaurants. Since its opening in 1875, this elegant hotel has hosted such world figures as seven U.S. presidents, Winston Churchill, Nikita Krushchev, Sarah Bernhardt, Enrico Caruso and Oscar Wilde.

ROOM RESERVATIONS

A large block of rooms has been set aside for attendees at preferred rates. However, we suggest you make your reservations early as delegate places and accommodations are filling fast. Rooms can be reserved directly with the Sheraton-Palace Hotel by calling 800-325-3535. Be sure to mention your participation in the NATURE 1985 Conference to qualify for special rates. Singles: $95. Doubles: $105 and $115.

CMEs WILL BE AWARDED

Extended Programs in Medical Education of the University of California School of Medicine in San Francisco designates this continuing medical education activity for 18 credit hours in Category 1 of the Physician's Recognition Award of the American Medical Association and the Certification Program of the California Medical Association.



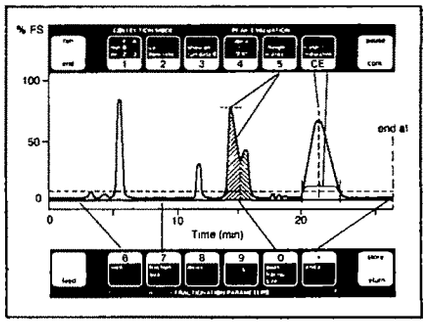
BURSARY PROGRAM

Bursary program for selected graduate students to be announced during August 1985.

POSTER SESSIONS

To have your poster considered, please include a working title and brief synopsis of your topic and send to Posters Editor, Nature Publishing Company, 65 Bleecker Street, New York, New York 10012

Everything rolled into 1



Pharmacia's FRAC-100 fraction collector

Do you need a simple inexpensive collector or the most advanced programmable fraction collector – get both with the FRAC-100.

Do you need fast tube changes and microliter collection volumes or is it 20 ml fractions from a 2 liter column? The FRAC-100 does both.

Do you need data handling and integration capabilities or do you want to choose from eight different collection modes and six fractionation parameters? The FRAC-100 does both.

Your everything solution in fraction collection is from Pharmacia.

Contact us today.

REDUCE BACKGROUND

With Sequencing Grade Triphosphates From Pharmacia

Ultrapure Deoxynucleoside Triphosphate Solutions

While often overlooked, high quality triphosphates can increase gel clarity considerably, allowing reading of up to 30 % further from a single primer site. Pharmacia's solution triphosphates are the most stable, homogeneous and diphosphate free nucleotides available In addition, they can be used without weighing, neutralization or concentration determination.

2′,3′-Dideoxynucleoside 5′-Triphosphates

Ever since we provided the first commercial dideoxynucleosides in 1977, researchers have relied on our ultra-pure 2′,3′-dideoxynucleoside 5′-triphosphates for the specific chain termination and low background needed in their sequencing

Keep your results clear of the background.

NATURE VOL 315 27 JUNE 1985

Put the horse before the cart

This week's European summit meeting at Milan is an opportunity both for stimulating technical collaboration and to create a muddle. Governments should temper enthusiasm with cold calculation.

EUREKA, President François Mitterrand's way of saying that he has seen the light for Europe, will occupy the European heads of government at their meeting in Milan this weekend. The plan is to invest common resources in technological developments that will help to bridge what Europeans used, in the 1960s, to call the "technology gap" between themselves and the United States. (Nowadays, Japan is as much in people's minds.) President Mitterrand has been preaching strength through technological development ever since he took office four years ago, but his most recent advocacy of this cause appears to have been stimulated by the fear that the US Strategic Defense Initiative, whatever its military implications, cannot fail to widen the gap between the competence of European companies and those in the United States. The discomfort of many European governments with the military and political implications of the US proposals has given Eureka a more hearty welcome than the earlier French initiatives (see *Nature* 6 June, p.443) It remains to be seen whether wrangles over budget problems and the high price of European grain will allow the heads of government time to put flesh on the bones of Mitterrand's dream. The big danger is that ill-considered enthusiasm will point this important enterprise in the wrong direction.

Here is a cautionary tale. While very little has been said of the way in which Eureka would be put into effect, one theme of the past few weeks has been that European governments should settle on a few major technical objectives and then pool resources so as to make them come to pass. What kinds of projects? On the face of things, a scheme to equip the air forces of Western Europe with a military aircraft designed to take over from those now in service would seem to be an obvious (if unambitious) candidate. As it happens, this is a scheme on which five European governments (Britain, France, Italy, Spain and West Germany) have already embarked. So what are the enthusiasts for Eureka to make of the meeting last week in London, when the governments concerned failed to agree on the specification of the aircraft they would jointly build, and on a scheme for sharing the construction work among themselves? That does not promise well for the simpler goal-oriented versions of Eureka, although there is a final meeting next month, at which something may be salvaged.

The lesson from last week's meeting is that it will make no sense for European governments to invest in the improvement of technology if they do not at the outset agree on the partition of the benefits. The temptation will be to attempt to divide the spoils in proportion to the investments made by the several governments, but attempts to legislate for chauvinistic equity along these lines are doomed to failure. Xenophobia being what it is, even within the European Communities, at least one but most probably all partners would finish with a sense of having been short-changed. The other more logical basis for mutual support for technological developments would be to say that the benefits of the investments proposed could be exploited by whichever European companies first had the wit to recognize their utility. In the long run, Europe as an economic entity would benefit, but some parts of it more than others. Equity would then require that there should be mechanisms for redistributing wealth among European states, which amounts to saying that Europe should function as a federated state Politically that is a long way from reality. If Eureka is to succeed this side of infinity, there will have to be some halfway house.

Much will depend on the kinds of projects on the agenda. So far, there have been only general statements of what might be done. People such as President Mitterrand have been talking of the further development of integrated semiconductors, of machines with artificial intelligence and, more recently, of the exploration of the deep oceans. On one view, the particular choice of projects to support is almost immaterial. Provided that the objective is sufficiently ambitious, the enthusiasts say, and Europe's engineers sufficiently committed, there will be a host of incidental technical developments which cannot fail to benefit European industry as a whole. This is the argument by which the 1960s Apollo programme to send people to the Moon was justified not by its ostensible objectives but by its technological spin-off. What this week's summit should remember is that such arguments are an assault on reason and a recipe for extravagance. If the technologies of, say, welding and refrigeration need to be improved, why not mount market-oriented developments in those fields? Especially when one of Europe's problems is a shortage of skill, the consequences of too much ambition could be a damaging diversion of resources.

Eureka should begin from a careful analysis of why Europe fails at present. The most obvious weakness is that Europe is not yet a common market. One result is that companies cannot accurately tell what research and development is likely to meet market needs. Another is that there are too many small companies duplicating each other's efforts. Eureka needs a way of circumventing these constitutional obstacles, perhaps by allowing separate companies to collaborate in transnational research and development partnerships that could be blessed with common funds. To work on what? The heads of government at Milan will no doubt be flush with ideas. They should keep them to themselves. Politicians and civil servants have a poor record as entrepreneurs What is needed is a mechanism by which groups of companies can put forward detailed proposals as if they were applying for research grants, but with the difference that the criteria for success would include not merely the novelty and the feasibility of the proposals, but some estimate of their economic and strategic promise. The European Commission's recent suggestion that the Euratom treaty provides a framework for channelling common funds into novel enterprises would make sense in this connection.

This week's summit must also give some thought to the infrastructure. One of the reasons why Europe's technology lags behind that of the United States and Japan is that its technological labour-force is ill-provided with first-hand demonstrations that the future can be made to happen here and now. Part of the trouble is that higher education is run on a shoestring (Britain) or is flexible (France and West Germany). Spending more on

Biological manuscripts

Contributors are reminded that, with the transfer of the Biological Sciences Editor to the Washington office, it will be helpful if they will in future send **four copies of all manuscripts** offered for publication, either (as at present) to London or Washington.

the university education of technical people is not a sufficient answer, although some of that will be needed. More to the point is the need that Europe, in trying to create the foundations for industrial prosperity in the next century, should find some way of enabling the now-young people who will inhabit that world to make their full mark. In many ways, Europe has grown too old.

The third need for the summit is to remember Adam Smith. Inward-looking Europeans see their enterprise as a self-contained imitation of what has already happened elsewhere. Too many Europeans consider that the immediate goal must be to replicate what IBM and AT&T have done in the United States, or what a host of Japanese companies have done in consumer electronics. The fallacy is that success would merely bring the prospect of head-on competition in fields that are certain to seem old-fashioned even a decade from now. But there is no reason why the world should become less interdependent than it is already, for which reason the trick for Europe must be that prosperity should rest on industrial activities complementary to those elsewhere. That is why the objective of those who endorse Eureka should be to build on Europe's present strengths, such as they are, not simply to imitate what others do. The goal must be an economic and economical division of labour, to which end originality is the crying need. Will the summit have the courage to recognize that simple but daunting truth? □

How many (what) miles?

Last week's shuttle flight shows that the Strategic Defense Initiative has a lot to learn.

THE timing of last week's fiasco in which a laser beam from Hawaii was directed at the wrong side of the US shuttle in orbit about the Earth could hardly have been worse. The US Congress is at the stage in the annual budget cycle when critics of the Strategic Defense Initiative (SDI) are energetically — and successfully — chipping away at the huge budget the administration has asked for. While nothing is settled, the chances are that the budget for the financial year beginning on 1 October will be reduced by between a quarter (according to the Senate) and a third (according to the House of Representatives) from the $3,700 million asked for. If the managers of SDI are wise, they will spend at least some of that sum on teaching each other a little about elementary goedesy.

The official explanation of the first failure of the laser test (which worked on later orbits) is quite breathtaking in its innocence. Almost merrily, the spokespeople have been saying that, by some oversight, the "on-board" computer on the shuttle had been programmed "in" statute rather than nautical miles. By their nudges and winks, thay have implied that only some profound perversity can explain the habit that has people who travel in shuttles measuring distance in the maritime measure of nautical miles. No doubt SDI officials will have figured out that nautical implies something to do with the sea, because *Nautilus* is a kind of submarine. In their innocence, they seem not to know that a nautical mile is intended to be the length of a minute of arc along a great circle on the surface of the Earth, although it was prematurely defined as 6,080 feet by the British Admiralty in the eighteenth century.

The SDI people are unlikely to be too downcast by this show of ignorance; they have earned a reputation for being brash. They have a tendency, when they encounter physical problems that would seem insuperable obstacles to others, to make a solution of them a "requirement" of the SDI programme as a whole. The little confusion between statute and nautical miles may, in any case, make them seek safety in unambiguously named kilometres instead (a cause too long dormant in the United States). So perhaps they should be told that the French Revolution had a committee, of which both Laplace and Lagrange were members, which defined the kilometre in much the same way as the nautical miles as one ten-thousandth of the distance between the Equator and the pole. □

Laser proliferation

The US Department of Energy thinks the laser enrichment of uranium feasible; that is bad news.

THE third review conference of the non-proliferation treaty (NPT), due to open at Geneva in August, will be forced to reckon with a late agenda item, the recognition that the simplest way of making nuclear weapons is probably now the enrichment of uranium by means of lasers. That is the implication of what appears to have been a successful demonstration of laser enrichment at the US Lawrence Livermore National Laboratory in California. The laboratory has been able to make five kilograms of uranium-235 in a single purification step. For those who wish to make bombs, the advantages of this route are obvious. Unlike isotope separation by gaseous diffusion or centrifugation, laser separation may be a once-through process. So capital costs are likely to be less and, for potential violators of agreements, separation plants will be inconspicuous.

None of this implies that uranium enrichment has become child's play. At Los Alamos as well as at Livermore, people have been trying for at least a decade to distinguish by means of lasers between the different isotopes of particular elements, with uranium usually at the backs of their minds. The fact that success has eluded them for so long is one comfort, suggesting that governments will not be able to run up material for a few bombs overnight by buying standard equipment from commercial suppliers. Indeed, the technology of copper excimer lasers reported (see p.706) to be the primary energy source for the Livermore process will not easily be replicated elsewhere, at least for the time being. In any case, crucial details such as the identity of the electronic transitions by means of which uranium atoms are excited to near-ionization are sensibly being kept secret. The obvious snag is that uranium atoms are the same the whole world over, and that the investigation of the spectroscopy of uranium required to specify the ingredients of a laser enrichment machine should be little more than few months' work for a couple of competent physicists. It is a fair guess that even governments with no interest in making bombs, but with an interest in what others may be doing, will put this work in hand immediately. Putative bomb-makers will probably be even quicker off the mark.

So does this new development mean that there is no longer any purpose served by attempts to control the spread of nuclear weapons by the physical control of fissile material? Fortunately, not quite. NPT is a compact between non-nuclear governments and the nuclear powers under which the first group undertakes not to make nuclear weapons, and to put up with physical inspection by the International Atomic Energy Agency, while the second undertakes not to help others make bombs but to help with civil nuclear technology, and at the same time to negotiate measures of arms control that will make the world a safer place. The signatory nuclear powers (France and China have not joined NPT) will be given another drubbing at this year's review conference for having done so little on arms control, but it seems unlikely that non-nuclear powers will desert the treaty on that account, or because laser enrichment seems to offer rivals outside the treaty a more convenient route to bomb-making. Keeping safeguards will be more than ever a demonstration of self denial.

The more serious problems are what they have always been, the abstention from NPT of countries which believe they may gain from being thought potential nuclear powers — Israel, Pakistan and so on. If laser enrichment means anything, it is that governments within NPT should have a powerful incentive not merely to control the use made of fissile material but also to see that the international trade in uranium is also well-regulated. For however convenient the new technique may be, it will still take the best part of a tonne of uranium to extract a critical mass of uranium-235, which should be a noticeable amount of such a scarce material. That is the direction in which the interests of the regulators should now be shifted. □

European research

Milan the spur to new collaborations?

Brussels

THE European Commission sees this week's summit meeting at Milan, where the French Eureka proposal is certain to have at least a brief hearing, as an opportunity for persuading the members of the European Communities to take a more serious interest in cooperative research and development But Mr Jacques Delors, president of the Commission, and his technology commissioner, Karl Heinz Narjes, are keeping an open mind on how collaboration might develop.

Delors wants flexibility above all, for which reason he is keeping up his sleeve several different legal frameworks for technological collaboration One possibility is that the existing Euratom treaty might suffice, another that there might be a new treaty along similar lines. But that, everybody agrees, would take too much time. The Commission seems to be saying that it merely wants the member states to agree to collaborate, leaving the details of collaboration to be worked out later.

According to Delors, money is all important. He insists that there should be a "critical mass" of funds for research and development. Part of his ambition is that member states should come to regard common spending on research as the European equivalent of US spending on military developments, where commercial beneficiaries are not expected to repay the public investment.

One mark of members' commitment will be whether they agree to the 14.9 per cent increases of the Communities' research budget marked out for 1986. Narjes believes that research and development will have to take a larger slice of the Communities' budget in future years, perhaps between 6 and 8 per cent of the total by 1990. Whether the member states will happily accept the implication of increased budget contributions to the Community is another matter.

Responses so far from member governments have been mixed, according to Narjes, who sees European initiatives in research and development as essentially collaboration on projects to which industrial companies would contribute, as in existing collaborations. While some governments are concerned at the prospect of Community control of common projects, the Commission notes that British companies have shown more interest than their government in the proposed collaborative programme, Research in Advanced Communications in Europe (RACE).

In its optimism, the Commission does not expect that its plans to expand collaborative research will founder on the expectation of member states of a return proportional to their individual investments. But changes will be needed in what governments expect. And there will also have to be more decisive steps towards the creation of a Europe-wide system of standards and a greater degree of cohesion so that it would be more difficult than at present for competitors elsewhere to "pick off" European states one by one.

Narjes does not expect more from this week's summit than agreement among the member states to settle on two or three projects for further collaboration by the end of 1985. He has a shopping list of areas in which collaboration might be sought, ranging from large computers and superchips to high-speed trains and biomolecular engineering to particle beam physics and optical communication. The Commission would like to see the French Eureka project subsumed in an agreement that Europe's collaborative research programmes should be expanded

Pragmatically, the Commission says that the legal forms of novel collaborations will be decided only after specific programmes have been agreed. One obstacle ahead, according to Delors, is that Europe's technical labour force is ageing more quickly than that of the United States and Japan The Commission's ambitious plans are in part intended to be a spur to the training of more skilled technologists, if only because partners in the new collaborations that may come into being will know that they will benefit only in proportion to the numbers of people able to help exploit the results of research and development programmes.

Anna Lubinska

Chemical weapons

US moratorium to end

Washington

THE US House of Representatives voted last week to end a 16-year moratorium on the production of chemical weapons. Actual production of the new "binary" weapons, which contain two relatively non-lethal chemicals that are mixed together in flight to produce nerve agent, could begin in December 1987.

The Reagan administration, arguing that current stockpiles of nerve-gas shells

are deteriorating and do not represent a "credible" deterrent, had repeatedly sought congressional approval for the new weapons over the past three years. In close votes, the House had repeatedly rebuffed the President. This time, however, heavy White House lobbying paid off. The Republican-controlled Senate had already approved the proposal.

Supporters did make several concessions, however Funds for production would not be released until 1987, and only after the President certifies that the weapons are needed. Supporters also accepted an amendment that would require the NATO (North Atlantic Treaty Organization) allies to declare their willingness to have the US weapons deployed in their countries before production could begin. However, even opponents of the new weapons expect that amendment to be dropped by a House/Senate conference which must meet to reconcile differences between the two houses' bills. Congress will still have to agree to appropriate the funds for production.

The House bill authorizes an initial expenditure of $124 million; the Senate bill, $163 million. Critics have said that the total cost of carrying out the Pentagon's production plan could exceed $4,000 million.

Stephen Budiansky

Nature in Japan

NATURE announces an international conference to be held in Tokyo next year, on 22–24 January 1986, on the theme *Molecular biology becomes biotechnology*. Speakers at the conference will include ten from the United States and Europe and an equal number from Japan. The conference, which will interest molecular biologists in academic and industrial laboratories, is in the series which includes this week's conference in London and that, in conjunction with the University of California, San Francisco, to be held in San Francisco next October. Further details may be had from *Nature*'s offices in London and Tokyo. □

Auto emissions

Europe nears compromise

Brussels

Too tough for some, too lenient for others, the Commission of the European Economic Communities (EEC) was last week required to defend its proposals to limit car exhaust pollution. At the same time, its experts began a last minute search for a compromise to avert an otherwise inevitable deadlock when the ten environment ministers meet in Luxembourg on 28 June. The compromise could involve not only a possible redefinition of the troublesome medium-range category of car (now set at 1.4–2.0 litres) but also different emission standards for cars fitted with three-way catalytic converters and those relying on lean-burn technology.

Reactions to the original proposals (see *Nature* 20 June, p.622) have been sharply divided among the member states. France, Italy and Belgium have joined the United Kingdom in dismissing the emission standards for medium-sized cars as too strict. But West Germany, followed by the Netherlands, Luxembourg and Denmark (which wants to see US-style uniformly strict controls applied to all categories of cars), is set on tougher controls. In addition, the Commission's proposals have reopened the debate on large cars (2 litres and over) that appeared to have been settled in principle on 20 March. The figures put forward by the Commission are unacceptable to Belgium, France and the United Kingdom despite the fact that the use of the three-way converter in the case of large cars had been agreed in March.

The Commission's proposals have also been sharply criticized by an outside expert, Dr Michael P. Walsh, former deputy assistant administrator for the US Environmental Protection Agency's mobile source air pollution control. In two papers made public last week, he maintained that the Commission's proposals ignore a number of important factors. In particular, they do not take account of increased car sales which, given the long timetable for implementing the proposals, could mean "significantly more pollution both in the short and long term".

According to Walsh, by the time the entire fleet is converted to the new standards, nitrogen oxide and hydrocarbon emissions will be almost three times more than equivalent US levels and carbon monoxide almost two and a half times more. "If member states choose to implement more 'permissive' standards, these estimates", he says, "are optimistic."

A major part of the problem is the test cycle used to establish the amount of pollutant emitted. The European test cycle, says Walsh, takes little account of modern driving conditions. A new European test cycle is being run at present, on the basis of which the standards now to be agreed will be modified in a year or two. This, Walsh says, will only serve to complicate the matter of laying down US-equivalent standards now.

The European Commission has always insisted that it is impossible to apply the US cycle to European cars. But Walsh says that European studies have shown that US test procedures are a more faithful reflection of current urban driving conditions. He concedes that the European test is effective in simulating dense congested traffic conditions, but says it will not suffice for assessing limits for NOX and hydrocarbons (which are generated at high speeds and carried over long distances).

Walsh maintains that the Commission's proposals as they stand will cut NOX emissions by only 39 per cent by the year 2010, while HC and CO emissions will fall by 24.4 per cent and 22.8 per cent. On the other hand, if US equivalent standards in the range of 4.6 grams per test HC plus NOX, 16 g/t CO and 2.4 g/t NOX were applied for medium and large cars, the actual reduction in pollution could be 66.7 per cent for CO, 75 per cent for HC and 76.7 per cent for NOX.

In response, the Commission has produced a paper supporting its proposed standards, which it says will reduce all car exhaust emissions by 70 per cent in the case of large cars and 73 per cent for medium cars, compared with 67 per cent reduction reached in the United States. Emissions of NOX, which are a principle concern of EEC, would be reduced to a level only slightly above that in the United States (1.56 million tonnes each year in EEC, compared with 1.48 million tonnes in the United States) with a further reduction possible when new limits (perhaps 5 g/t) are introduced during the planned second phase for small cars under 1.4 litres, bringing EEC emissions down to 1.41 million tonnes.

Commission experts estimate further that if EEC ministers agree to introduce US-type speed limits of 55 m.p.h. (88 k.p.h.) as well, global NOX emissions from Community cars could fall to 15 per cent below US levels. But this suggestion has so far been blocked by West Germany, whose cars incidentally emit the greatest volume of NOX (637,000 tonnes in 1980) and which is under the greatest pressure to adopt tough controls on air pollution. **Anna Lubinska**

Mount Wilson's end

Washington

No rescue plan has materialized to save the Mt Wilson 100-inch telescope, due to be shut down next week by its owner, the Carnegie Institution of Washington (CIW). Although discussions are continuing to find a "suitable operator" to take over the facility, it seems increasingly unlikely that one will be found. The several rescue groups that had been formed by interested astronomers, professional and amateur, have apparently failed to raise the several million dollars necessary to keep the telescope in operation.

Carnegie announced its intention to close the telescope a year ago, citing the increasing financial burden of running both Mt Wilson and its newer Las Campanas observatory in Chile. More recently, CIW revealed plans for shutting down the other astronomical facilities at Mt Wilson. The 60-inch reflector, now used for solar and stellar observations, will continue operating until 1 July 1986. The solar observatories will continue operating only until next October, but CIW is willing, until 1 July 1986, to continue administering salaries and other operational budgets provided by outside grants. In other words, CIW offers a nine-month lease to outside investigators who can find their own money. Stephen Budiansky

Verification in space

Los Alamos, New Mexico

Donald Kerr, director of Los Alamos National Laboratory, is calling for the United States to give more attention to how it would detect and assess new high-technology Soviet anti-missile defences — in other words, a Soviet star wars system. Kerr says that "the possibility should be anticipated" that the United States and Soviet Union might reach agreement to limit star wars defences, and points out that the first requirement of any such agreement would be a means of verifying compliance. Conventional reconnaissance might not be adequate to assess the capabilities of a Soviet star wars system.

Despite the new technical challenges of such a monitoring system, Kerr says he is "moving in that direction". The testing of laser weapons might be detected by looking for atmospherically-scattered repetitive pulses of light, for example, and satellites might be interrogated with particle beams to see if they contained fissile material: the radiation emitted would provide information on the isotopes present.

Kerr plans to argue his case in Stockholm next month at a conference on space weapons and international security hosted by the Stockholm International Peace Research Institute. Los Alamos National Laboratory has long undertaken research into ballistic missile defence and claims to be well placed to develop means of verifying compliance with anti-ballistic missile or other future treaties limiting arms in space. Tim Beardsley

Blood typing

US sale of British reagents

BLOOD-GROUP typing in the United States is likely to be based on monoclonal antibodies, following a deal between Celltech, the British biotechnology company, and Ortho Diagnostic Systems Inc., the Johnson & Johnson subsidiary which is the largest supplier of blood-typing reagents in the United States.

Although the British National Health Service has already switched over to Celltech's monoclonals for ABO blood typing, the technology was not simply transferable to Ortho The US blood-typing test is differently and more rapidly performed than the British test. Moreover, Ortho's blood-typing reagents, based on antibodies from donated blood, are designed to detect blood group antigens at below the threshold at which British tests operate.

These demands have required a two-year period of development by Celltech, with support from Ortho. Because the single monoclonal antibodies against blood groups A and B developed for use in Britain did not perform adequately in the US tests, Celltech embarked on a worldwide hunt for more appropriate antibodies. Despite screening hundreds of candidates, it failed to find sufficiently sensitive single A and B antibodies. So Ortho's reagents are each a cocktail of several monoclonals, some of which Celltech have had to buy in from outside. At least one unnamed US academic laboratory stands to gain.

There have also been regulatory hurdles to cross Because traditional blood-typing reagents are blood products, they are licensed by the Office of Biologics of the US Food and Drug Administration. The monoclonals, although derived from cultured cells rather than blood, have been caught by tradition and subjected to the regulations of the Office of Biologics, although other diagnostic monoclonals have passed through other offices.

Material is at present produced in 100-litre fermenters, but as Ortho's demand builds up, Celltech plans to switch to its 1,000-litre fermenter which can yield 100 grams of antibody in a two-week run. If, as expected, monoclonals are eventually used in half of ABO blood-typing tests worldwide, "a low number of kilograms" of antibody will be needed annually. According to Gerard Fairtlough, chief executive of Celltech, independent estimates put the world market for blood-typing reagents at £7.5 million per year. The initial agreement between Celltech and Ortho is for five years, involving payments of "several million pounds" to Celltech by Ortho.

John Berriman of Celltech sees no obvious competitors One Canadian and one Swedish company have potentially suitable monoclonals, but not Celltech's ability to produce them in quantity. Celltech also hopes to produce a monoclonal antibody for rhesus blood typing, but because mice do not produce antibodies against the human rhesus antigen, it has not been possible to use standard hybridoma technology. Instead, Celltech hopes to develop a system of producing a monoclonal antibody against D antigen, the main rhesus antigen, in human lymphocytes transformed by Epstein–Barr virus. **Peter Newmark**

Searle deals blow to Genex

Washington

GENEX Corporation, which had pinned its hopes for making an early profit on mass production of the chemical L-phenylalanine, the key starting material for the artificial sweetener aspartame, has been dealt a major setback. G. D. Searle, which holds exclusive rights in the United States and most of Europe for the use of aspartame as a sweetener, last week informed Genex that it would be dropping its contract to purchase phenylalanine as from November. Genex is left with an $18 million plant that the company says it built on assurance from Searle that it would continue to be a major supplier. The plant, located in Paducah, Kentucky, was completed only last year and it reached full production three months ago.

Genex's president, J. Leslie Glick, acknowledges that the market for other uses of phenylalanine, mainly the production of pharmaceuticals, is "limited", and could not justify keeping the Paducah plant open.

Genex last year had sales of $20.6 million, almost all of that from phenylalanine. Research and development contracts, which totalled $5.7 million last year, will now once again become the company's major source of revenue. Glick said the company was looking into the possibility of using the Paducah plant for enzyme production or for joint ventures. Only 25 per cent of the facility is now used for phenylalanine production. The company had been reserving the remaining space for expansion in other areas.

Glick says that Genex's loss for 1985 would be less than last year's despite the setback, largely because the high cost of starting up the Paducah plant was included in last year's accounts. Searle refuses to comment on the decision not to renew its contract with Genex. Searle is known to have expanded its own capacity for producing phenylalanine and it also purchases an undisclosed quantity from Ajinomoto in Japan. Genex's process involved an enzyme reaction of cinnamic acid. Ajinomoto (and Searle, which licenses the process from Ajinomoto) uses selected strains of bacteria and fungi that produce large amounts of phenylalanine from sugar.

Searle patents on the use of aspartame expire in the United States in 1992 and in Europe beginning in 1987. Genex's plant is producing about 2,000 metric tons of phenylalanine a year, about two-thirds of Searle's current need, according to independent estimates. It is estimated that by 1987 the demand for phenylalanine will be 5,700 metric tons per year. Searle's sales of aspartame last year were worth a total of $585 million. Stephen Budiansky

AIDS

France to screen blood donors

FRANCE could begin testing all blood donors for antibodies to the virus causing AIDS (acquired immune deficiency syndrome) "within a week", and donors may be told the results. This dramatic action to limit the spread of AIDS in France is presaged by the announcement by the Prime Minister, Laurent Fabius, in the National Assembly last week that, "after much reflection", he had decided that a test must be "obligatory".

The tests will be carried out by the blood transfusion service SNTS (Service Nationale de Transfusion Sanguine), which has been evaluating three different commercially available tests. One is French, prepared by the Institut Pasteur and marketed by the drug company Sanofi, and two US — one from Abbott Industries and the other from Electro-Nucleonics (distributed in Europe by the Dutch company Organon). All three tests are based on the ELISA technique (enzyme-linked immunosorbent assay) using killed virus. Because of the loss of envelope protein during the preparation, all of them are more sensitive to antibody to the virus inner protein (*gag*) than to the envelope protein antibodies.

Exactly which test will be selected is not for SNTS to decide, but Fabius spoke favourably last week of the French product, "which could be exported throughout the whole world". SNTS say that tests could begin within a week, although Fabius himself did not announce a date. He did, however, indicate a cost — FF 200 million (£20 million) a year.

On the question of informing donors if AIDS antibody is detected, Fabius is not yet convinced. He has asked for a "more detailed" analysis, and has set up a committee of experts to report to him as soon as possible. The tests are necessary, but unnecessary fears should be avoided, he said. **Robert Walgate**

Thermonuclear fusion

Inertial confinement in trouble

Washington

ANTARES, the world's most powerful fusion research laser, could face premature retirement later this year after only two years in operation, unless the US Congress takes pity on the $63.5 million instrument. The laser, at Los Alamos National Laboratory, is being used for experiments in inertial confinement fusion, but has proved to be the instrument of its own fate: it has clearly demonstrated that carbon dioxide lasers such as Antares have no potential for economic fusion. Hopes of a reprieve are now pinned on the possible use of Antares in the Strategic Defense Initiative (SDI) programme of research into anti-missile defences.

Antares is capable of producing a 40-kilojoule pulse of light lasting for one nanosecond. The problem is that radiation of wavelength 10.3 micrometres is, with the benefit of hindsight, too long for economic fusion power. When focused onto a glass bead containing fusion fuel, radiation of this wavelength stimulates the emission of hot electrons that pre-heat the fuel and so prevent the high degree of compression and simultaneous high temperature needed to achieve plasma ignition. Carbon dioxide lasers would be useful only if their cost dropped drastically, to about $10 per joule. This is an unlikely prospect; Antares costs $1,500 per joule, and the cheapest imaginable mass-produced carbon dioxide laser would still cost $300 per joule.

The administration's inertial confinement fusion budget request for fiscal year 1986 assumes that Antares will be taken out of service before the end of 1985. The total request at $70 million is about the figure for the current year. Donald Kerr, director at Los Alamos, has testified before Congress that about 100 people may lose their jobs in inertial confinement fusion if the proposed cuts go ahead.

David Cartwright, principal programme manager for inertial confinement fusion at Los Alamos, has recently informally requested an extra $5 million to allow the current series of experiments on Antares to be completed, because recent results suggest that the temperature of the troublesome hot electrons can be reduced by increasing pulse duration from about 1 nanosecond to 5 nanoseconds. This sum would nevertheless keep Antares in operation for only a few months, and would not allow modifications for new experiments. Hence the hopes that the SDI organization might take an interest.

Cartwright says Antares is the only national facility that could be used to test the predicted effects of high intensity laser radiation on nuclear warhead re-entry vehicles. The pulse length and power could without much difficulty be increased to a few microseconds and 0.25 megajoules, a region of importance for laser weapon concepts. Mirrors would have to be repositioned so that, instead of converging in three dimensions on a single point, the laser beams would illuminate a larger spot from one side. A request for $15 million has been made to the SDI organization for this purpose. Antares might also be used to drive X-ray lasers, also of SDI interest.

Congress is sympathetic to the idea of keeping Antares running, and both houses have authorized sums of around $145 million for inertial confinement fusion — twice the administration's request. The appropriations hearings, which will decide how much will actually be spent, have, however, only just started.

Some support for Antares has come from the National Academy of Sciences, which is carrying out for Congress a study of inertial confinement fusion. The committee responsible has made known its opinion that it would be unwise to dismantle a facility while its usefulness is still being evaluated. Congress might therefore take this cue to override the Office of Management and Budget, as it has been known to do before. Congressional aides warn, however, that there may be jurisdictional obstacles to supporting Antares directly through the SDI organization, if only because that would entail a transfer of funds between two subcommittees. On Capitol Hill, subcommittees' territories are guarded jealously, and the political difficulties are seen as far more daunting than the technical modifications that Antares itself would need.

The other major fusion research laser facility in the United States, known as Nova, is close to completion at Lawrence Livermore laboratory. The light produced by the neodymium-glass lasers in Nova has a wavelength of around 1 micrometre, but is then frequency-multiplied by a factor of 3 to give light with 0.35 micrometre wavelength. Even this is not expected to

Uranium enrichment

France also plumps for lasers

THE French nuclear fuel company, COGEMA, announced earlier this month plans to enrich uranium by laser, rather than by the diffusion or centrifugation of uranium hexafluoride gas, and said that this would cut costs by a factor of two. But one French observer says the statement is a "bluff" prompted by competition with the United States for the supply of enriched uranium to Japan and by a wish to pre-empt the announcement by the US Department of Energy of its decision to adopt the laser process.

Research on laser enrichment has been under way at the laboratory of the Commissariat à l'Energie Atomique at Saclay, near Paris, for some years. But the feeling in France appears to have been that the technique was not yet required, so that the project has been poorly supported. According to M. Claude Bearnaud, director of the isotope separation research unit at Saclay, it will be 15 years before full-scale laser separation plants are in operation.

Bearnaud spends some FF 100 million (about £9 million) a year on laser separation experiments with the French SILVA process, which is similar to the AVLIS process, developed by Lawrence Livermore Laboratory in the United States, using uranium metal vapour. But following the COGEMA announcement, he expects his budget to rise next year by some 20–30 per cent, taking SILVA to the "pre-pilot phase". The separation of kilogram quantities of uranium will come only later, Bearnaud says. The Lawrence Livermore Laboratory, after a year's frantic competition with the Oak Ridge advanced gas centrifuge, has now claimed the successful enrichment of some five kilogrammes of uranium.

Even so, says Bearnaud, there is no commercial need for a laser plant as yet. So why the US haste? One British laser physicist believes the spur may be the need to accumulate separated plutonium for the increasing numbers of US multi-warhead (MIRV-ed) missiles. In these missiles space is at a premium, and plutonium, with a lower critical mass than uranium, makes smaller triggers. The United States has plenty of plutonium in spent fuel from its 90-odd pressurized water reactors, but that is contaminated with isotopes which dampen the fast chain reaction which is essential in warhead applications.

AVLIS, or SILVA, could help. The principles could be applied to any isotope system, but Bearnaud says he is not at liberty to say if his group has worked on plutonium.

For commercial uranium separation, on the other hand, French sources are more forthcoming. Estimates are that the optimum size of a laser plant will be some ½–1 million units "separative work" (SWU) a year, enough to supply three to six 1,000-MW pressurized water reactors with fuel. By comparison, the giant Eurodif diffusion plant at Tricastin in France is capable of nearly 11 million SWU a year, but is under-utilized. Laser separation will be cheaper in the long run, according to Bearnaud. Indeed, COGEMA is said to have offered in Japan to halve future enriched uranium prices.

Robert Walgate

be economically viable for fusion; the best hope among lasers is probably the krypton fluoride excimer laser, which has a wavelength of 0.25 micrometres and which has been developed since work on Antares and Nova began. Los Alamos has a small experimental krypton fluoride laser known as Aurora. Many now believe, however, that light ion beams will beat lasers to achieving plasma ignition. What might be the first machine to reach plasma ignition, known as Particle Beam Fusion Accelerator-2, will begin tests early next year at Sandia National Laboratory in New Mexico. **Tim Beardsley**

Proliferation

THE atomic vapour laser isotope separation process (AVLIS), chosen by the US Department of Energy for separating the fissile uranium-235 isotope from natural uranium (see above), relies on selective three-photon ionization in an electric field, which sweeps out the ionized uranium-235.

Success depends on the relatively large (1 GHz) isotope shifts of spectral lines of the actinide elements on the low thermal velocities of such heavy atoms (implying reduced Doppler broadening) and the use of laser beams impinging perpendicularly on a collimated jet of uranium vapour (reducing Doppler effect still further).

In principle, the excitation could be effected in two steps, by a photon carefully tuned to an internal excitation and a photon of almost any wavelength to take the excited electron out to the continuum, leaving the atom ionized. But the ionization energy of uranium-235 is so high that the two photons would have to be at the blue end of the spectrum, where tunable lasers are expensive and where photons tend to degrade laser mirrors. So AVLIS uses instead two low-energy mid-spectrum photons, produced by a dye laser, to effect the finely-tuned selective excitation. A third ultraviolet photon is then used to take the excited electron far out into the continuum, where auto-ionization resonance increases the ionization cross-section tenfold.

The use of two successive excitation photons also has the advantage that each can be fired from different sides of the uranium jet, so that the first-order Doppler effects cancel. The Lawrence Livermore dye lasers are pumped by a high-efficiency high repetition-rate copper-vapour laser which has the advantage over continuous lasers of an extremely high average power.

According to one British laser physicist, such devices "could be run in a university laboratory" to separate kilogram quantities of fissile uranium-235. If a dye-laser system were established in Libya, for example, "it would be invisible", which is "why we're worried about them".

Hubble telescope

Space institute's wings clipped

Washington

A STUDY of the Space Telescope Science Institute (STSI) by a National Research Council task group has concluded that the ever-expanding institute should not be allowed to grow much beyond its present size. The study, which was commissioned by the National Aeronautics and Space Administration (NASA), says that new scientific functions required for the Hubble Space Telescope should instead be contracted to outside organizations, with STSI restricted to an advisory role wherever possible.

The task group undertook its study in the light of widespread concern in the

astronomy community about the institute's rapid growth since it was established in 1981. NASA originally planned an institute with a staff of 100 and an annual budget of less than $5 million; STSI's budget for this year, however, is $12.8 million and is expected to reach $21 million by the end of the decade (at 1984 prices). The staff already numbers over 200 and is expected to top 250 before long. Some fear that the institute might squeeze out other NASA astronomy projects.

The task group, chaired by William Gordon of Rice University, agrees that NASA's original idea of having a special institute to manage science for the space telescope was a good one, and says the institute, which is based at Johns Hopkins University, has done a good job of surmounting the many unplanned technical obstacles that have beset the space telescope. But the task group euphemistically suggests that STSI's stated objectives should be modified by adding a requirement that STSI work "within available resources". What those available resources should be is not specified, although the task group notes that STSI was intended to be comparable in size with other ground-based astronomy facilities; that being the case, STSI is already close to the upper limit.

Gordon's task group also has some implied criticism for the Association of Universities for Research in Astronomy (AURA), the organization that is nominally in control of STSI. Gordon says that AURA should play a more active role in mediating in the frequent jurisdictional conflicts that have arisen between NASA and STSI.

Other recommendations include the suggestion that STSI develop remotely accessible data archives and software that can be run on computers at researchers' home institutions, to avoid pressure on computer time at STSI. The task group also says NASA and STSI should plan a joint public information service for when the telescope is operational. In the longer term, however, Gordon says it is up to NASA to make clear its plan for the future of the institute. **Tim Beardsley**

The report, Institutional Arrangements for the Space Telescope: A Mid-Term Review *is by the Committee on Space, Astronomy and Astrophysics, National Research Council, Washington, DC.*

East German physicist

Absence noted

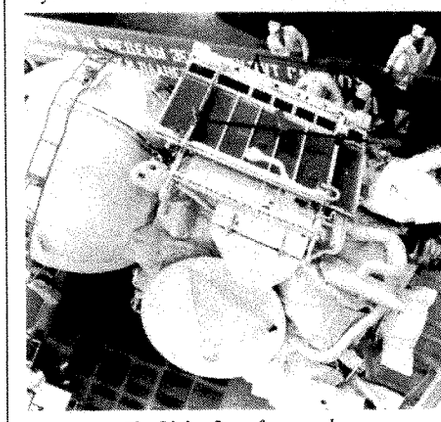
AT a physics conference in Visby, Sweden, this month, Dr John F. Sharpey-Schafer from the University of Liverpool announced that his paper was dedicated to Dr Stefan Frauendorf of the Zentral Institut für Kernforschung at Rossendorf, East Germany. Dr Frauendorf had been invited to read a paper at the conference, but was arrested last November, and is now said to be facing charges of espionage, based on alleged contacts with West German intelligence services.

Dr Frauendorf had for several years been a regular visitor to the Niels Bohr Institute in Copenhagen, where he was working with several other scientists on a joint project on nuclear structure.

At the time of his arrest, he was in the process of reading and correcting a paper, written jointly with the Niels Bohr team, on high spin states. This paper seems to have disappeared at the time of his arrest and, as there was no copy, much work has had to be redone. A letter from the Niels Bohr Institute, enquiring about the paper and deploring the breaking off of collaboration with Dr Frauendorf, brought only the answer that the physicist was under investigation for espionage carried out over a number of years.

The Niels Bohr Institute has been working with Rossendorf for some 20 years, an association which has been especially fruitful over the past five years or so, roughly the period of Dr Frauendorf's visits. Cooperation arrangements have not been entirely broken off by the incident, however; three further visitors have arrived from Rossendorf since the scientist's arrest. **Vera Rich**

Venus



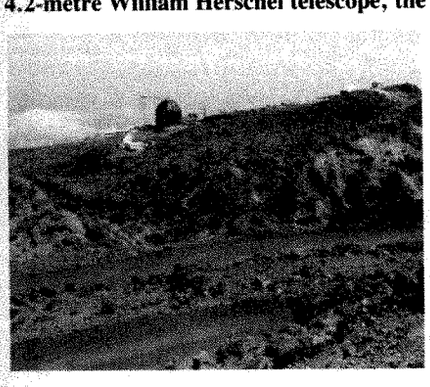
Soviet probes make soft landing

THE first part of the Soviet Veha (Venus-Halley) mission, the descent of atmospheric and surface probes to Venus, has been a success, according to Dr Vladimir Kotel'nikov, first vice-president of the Soviet Academy of Sciences. Indeed, in good Soviet style, the Veha-2 surface probe, which included a rock-gathering minidrill and spectrometer analysis chamber, overfulfilled its norm, working and transmitting data for 22 minutes and 17 seconds rather than for the expected 14 minutes. "Express analysis" of incoming data, moreover, revealed a number of new results, both confirming previous postulates and producing various surprises.

The Veha-2 descent module, which landed in the Rusalka plain (6°27′ S. latitude, 181°5′, longitude), has revealed the presence at that point of soft sandy soil. Previous missions had revealed a more rocky terrain and, although several planetary podologists had postulated that more friable soil might be encountered, this is the first direct evidence of them. Similarly, the two drifting aerostatic probes (carried by helium balloons) directly confirmed the presence of large quantities of sulphuric acid in the venusian clouds. These two probes drifted around the planet's equator for a quarter of its circumference, with a translation velocity of 60 to 70 metres a second. Surprisingly, the balloons encountered updraughts and downdraughts of up to 1 m a second, which hurled them up and down by 200 to 300 m. The drift data from the probes, which were tracked by radio telescopes at Medvezh'i Ozera and Ussriisk in the Soviet Union, Pentikton (Canada), Fort Davis (United States), Madrid, and Parkes (Australia), will be processed in conjunction with the CNES centre at Toulouse. Full results are not expected before the beginning of 1987. At the press conference at the Space Exploration Institute of the Soviet Academy of Sciences last week, speakers stressed that even the initial data "leave no doubt" of the "powerful circulation" in the venusian atmosphere.

This press conference and the approach of the Soviet media in general to this, the first major space event of the Gorbachev era, is instructive. TASS reported the mission without its well-worn formula that this research was carried out in accordance with the directives of the 22nd Party Congress on the application of space to the national economy, which suggests a deliberate effort to take the public into the scientists' confidence.

One radio transmission at 16.30 Moscow time on 15 June took the form of a report from the flight control centre, suggesting that it was happening in real time. An interview with Dr Valerii Barsukov, director of the Vernadskii Institute of Geochemistry and Analytical Chemistry, on volcanism on Venus was "interrupted" by an announcement that Veha-2 had landed. The effect may have been spoiled for discerning listeners by the fact that shorter and less dramatic announcements of the Veha-2 landing earlier that day had also been given out on radio in real time style.



The Veha-2 surface probe.

For the rest, the official spokesmen have stressed the international aspects of the mission. France has participated in providing the apparatus for the aerostatic probes and landing craft, while the Halley's comet part of the mission will involve equipment from "a large number of both socialist and capitalist countries".

CERN

Schopper's views on Kendrew

REACTIONS last week to the Kendrew report on the future of British participation at CERN, the European Organization for Nuclear Research (see *Nature* 20 June, p.619), at least from particle physicists in Britain and Europe, are most diplomatically described as a blend of acute scepticism and puzzlement. The scepticism is that a combination of broader international membership and a reduced budget could possibly lead to a 25 per cent reduction in the cost of CERN by the deadline set for 1991, and puzzlement that somebody with Sir John Kendrew's experience of running the European Molecular Biology Laboratory at Heidelberg could ever have thought his panel's recommendations practicable.

Professor Herwig Schopper, the director-general of CERN, while saying he was glad that the report was very positive about the science and management of CERN, emphasized the implications of the recommendations. "Increased membership is not a new idea; some international collaborations have associate members linked to only parts of their programmes, but we have only one major programme [the construction of the electron–positron collider LEP]. Wider membership is a possibility for the future".

A major hindrance to widening CERN's membership in the near future, it seems, is that countries such as Japan and Canada (mentioned by Kendrew last week as possible candidates) would not be attracted by LEP given the advanced state of its development. Looking much further ahead, however, the proposed construction of the Large Hadron Collider in the LEP tunnel would necessitate a significant increase in CERN's budget, and that project could attract a wider membership.

The proposed cut in the cost of CERN of 25 per cent by 1991 would, in the circumstances, have to come from reduced contributions from the member states. Schopper points out that about half of the budget goes on salaries. "CERN's council could decide on lower salaries for new arrivals, but current recruitment rates are low. A decision to reduce existing salaries could result in our being taken to court." So, Schopper says, a 25 per cent cut in CERN's budget would have to come almost entirely from the materials budget, and would effectively emasculate CERN. There is no sign, moreover, that other member states would approve a significant budget cut. "This seems to be a special British problem", said Schopper.

Philip Campbell

British geophysics

Royal Society backs protest

THE management and financial support for geophysics research in Britain are inadequate, while government support is "poorly coordinated, even capricious". This is the theme of the report of a working party on geophysics research set up by the Royal Society under Professor E.R. Oxburgh (Cambridge). The group's report, *Support of Geophysics in the United Kingdom*, published last week, has been endorsed by the Royal Society council.

The starting-point for the working party's argument is what it sees as a mismatch between the rapid growth of reflection seismology surveys for economic prospecting, on which $3,000 million was spent worldwide in 1982, and the scale on which basic geophysics is supported. "If there is one message we wish to convey, it is that geophysics matters to the country", said Oxburgh last week.

The report gives a gloomy account of lost opportunities in British geophysics. The next phase of the Deep-Sea Drilling Programme will "go ahead without British participation" for lack of £2.5 million a year. Except on a "private basis", British scientists will not be involved in the use of the worldwide seismic networks being built by the United States and France for modelling the inner structure of the Earth. It would be "unthinkable . . . at present" to propose British participation in the deep continental drilling programmes being mounted by West Germany or the deep-sea submersible projects of the United States and France. Noting that British geophysicists have in the past done well in elections to the fellowship of the American Geophysical Union, the working party says that the figures also show that "significant numbers of geophysicists have chosen not to work in Britain".

In its analysis of what has gone wrong, the working party says that an estimated 110 academic geophysicists and perhaps as many postdoctoral workers are distributed "in small groups or as isolated individuals" in university departments of physics, geology and even applied mathematics. The report asks for a "greater concentration in fewer centres", offering as models the Mullard Space Science Laboratory of University College, London, and the Robert Hooke Institute for Atmospheric Research at Oxford.

The mechanism of government support for geophysics research is the other chief cause of trouble. The Oxburgh group suspects that the British geophysics community may be too small a constituency of the Science and Engineering Research Council (SERC), which spent £1.2 million on geophysics research grants in 1983–84. This is nearly three times the value of the grants awarded by the Natural Environment Research Council (NERC), most of whose support for geophysics goes on its own institutes and on collaboration ventures.

The working party is stinging in its criticism of NERC (see below), although sympathetic about the council's difficulties. The chief of these is the erosion of commissions for research at NERC institutes from government departments, which is reckoned to have declined from £25 million to £15 million (at present prices) in three years. NERC has suffered "not only its own budget cuts . . . but also enhanced cuts in its contractual income from customer departments".

One result, the report says, is that NERC has been "obliged" to concentrate on work that brings in outside income "with less regard to the scientific content" and often in competition with others. The working party also says that the ability of the institutes to "compete in the marketplace" has been constrained by labour legislation and trades union agreements, citing the way in which the British Geological Survey (the largest institute) has been compelled to take onto its permanent staff a number of people originally hired for short-term projects.

In general, the report says, NERC support for its geophysics institutes ranges from the "marginally satisfactory . . . to the derisory". The Oxburgh group is especially concerned about the danger that geophysical survey work is being neglected. It says that geophysical surveys in the South Atlantic were drawn on by the British government during the Falklands war, contributing to an unquantifiable "saving in lives". The report goes on to say that "strategic national interests are involved, and it is not right that such decisions should depend on the funding priorities of a particular government department at a particular moment".

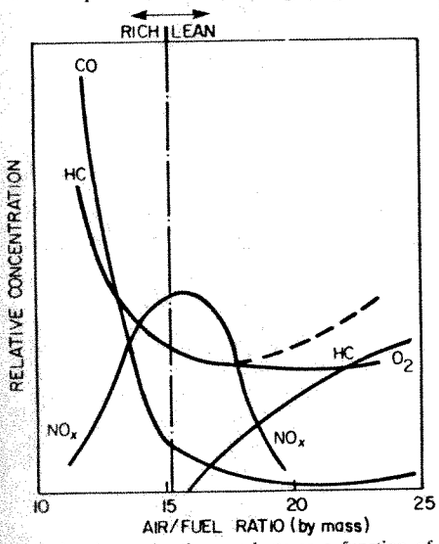
Noting that the funds made available for new research projects in geophysics have declined by half over the past five years, the working party says that one consequence has been "a pervasive pessimism and loss of morale" among researchers.

The working party is also critical of the lack of coordination between research councils and government departments. Projects falling between NERC and SERC face a "double hazard", where each council has to commit funds before work can go ahead. The report cites the "discouraging history" of a satellite laser-ranger suggested by the Royal Greenwich Observatory, where one council was prepared to meet the high capital cost but the other unable to afford the running costs.

In resignation, the working party turns from British orthodox sources of funds to those that might be found elsewhere. On the basis that much future geophysics will hang on satellite observations, the Oxburgh group asks for greater involvement by the British Department of Trade and Industry, and urges the setting-up of a space research directorate (which has since been agreed). It asks that there should be closer coordination with the military on geophysical problems of mutual interest, and says that British geophysics should take advantage of the interest of the European Commission in the geophysics of energy problems. The report says that industrial companies should spend more on the support of British geophysics, and that problems of commercial secrecy are by the Norwegian experience not the impediments to collaboration they are often said to be. □

NERC pilloried

THE Oxburgh group's criticisms of NERC include the following.



- **"The council, or some of its officers, sees itself as now directing research programmes rather than facilitating research in institutes and universities."**
- **The cost of NERC's central scientific services (mainly a computing network) seems to be too high (at £6 million a year) compared with that on other facilities and decisions about NERC services "are still being made without being approved by appropriate scientific committees".**
- **On the allocation of research vessel time to university scientists, the Oxburgh group complains that people cannot plan ahead. Shortly before the new research ship *Charles Darwin* was delivered last year, NERC laid up most of its other research vessels, forcing academics to put off planned observations. Because allocation of ship-time and running costs are made by different committees, investigators may be blessed with ship-time "but not the much smaller sums" required to make use of it.**
- **The group is concerned about the functioning of NERC headquarters. "We are astonished" at their involvement in minor matters . . . "Directors are not being allowed to direct." Apart from the unregulated growth of the computer network, the group is concerned that active scientists on the council and its committees are not "effectively involved" in the disposition of financial resources. Not surprisingly, the group raises the question whether NERC should continue to be responsible for supporting university research, says that the style of headquarters management makes NERC seem "bureaucratic and insensitive" and asks, as one of its principal recommendations, that the Advisory Board for the Research Councils should consider what should be done.**

In a statement put out earlier this week, Mr Hugh Fish, now confirmed as chairman of NERC, said that he took "great exception" to parts of the report (but a spokesman declined to say what these are). Mr Fish said he plans "to do no more" than seek a discussion of the report with the president of the Royal Society. □

Pollution from automobiles

SIR — A recent article by A. Lubinska[1] discusses the relative merits of catalytic converters versus lean-burn engines. In that comparison she states that "The high air/fuel ratio of the lean-burn engine lowers both carbon monoxide and nitrous oxide emissions, but increases hydrocarbon emissions...."

Nitrous oxide, N_2O, is emitted only in small quantities by internal combustion engines, while nitric oxide, NO, is produced in large quantities[2]. In addition, N_2O is inert in the lower 10 km of the atmosphere while NO plays a major role in both photochemical smog (O_3) formation and acid deposition. She appears to have confused the two gases.

Variation in combustion products as a function of air/fuel ratio[4,5]. NO_x is the sum of NO and NO_2; these two compounds are rapidly interconverted in the atmosphere. The dashed line shows the result of misfiring.

More importantly the article tends to oversimplify a complicated issue. Lean-burn engines have advanced significantly in recent years, but they are technically complex and not immediately available for mass-production. Not all types of vehicles are suitable for lean-burn engines; the increase in gasoline (motor fuel) economy is accompanied by a decrease in power.

As the air/fuel mixture becomes leaner (higher on figure), NO emissions increase before they decrease. Lean-burn engines must run at an air/fuel ratio of 22 to 25 before nitric oxide emissions are significantly reduced. At such lean mixtures, ordinary engines misfire and hydrocarbons rise dramatically. A lean-burn engine must have an efficient fuel-injection system to avoid misfiring[6]. The more advanced fuel injection system and other modifications add to the price of an automobile, expenses neglected in Lubinska's article.

Catalytic converters are more readily available than lean-burn engines but even the implementation of catalysts in European cars is non-trivial. They have been used successfully in the United States but Europe offers more extreme driving conditions. There are more congested cities where the catalyst tends to be too cold and autobahns where routine speeds approach 160 km per hour (100 miles per hour) and the catalyst tends to be too hot.

Lead, even in very small amounts, poisons catalytic converters. In the United States, unleaded gasoline is federally mandated and nearly all driving is within national boundaries. In Europe, where drivers frequently cross national borders, lead-free gasoline may not be uniformly available.

In summary, lean-burn engines are a promising alternative to catalytic converters, but they too have problems. The reduction of air pollution from automobiles is not simple, and a variety of techniques is sure to be needed.

Research councils

SIR — Whatever the faults of Whitehall, it is never lost for ideas to make research councils more efficient. Last year the Comptroller and Auditor General[1] warned that by appointing the best candidate for the job, the research councils were being flooded with staff of unnecessarily high calibre. This was part of the wider problem of fluid grading. Several research councils, although not the Medical Research Council (MRC), were guilty of basing promotion on the ability of the individual, rather than the name of the job. These suggestions were made in all seriousness and the research councils have duly promised to mend their ways.

It has now been realized that what research councils need, to make them more effective, is flexibility through more short-term and fewer career appointments[2]. It is well known that a civil servant who shows signs of starting to understand a job must be moved on as quickly as possible. This strategy, which has done so much for the British civil service, could well be expected to transform the work of the research councils.

There are one or two difficulties. The Advisory Board for the Research Councils has itself pointed out[2] that scientists on short-term contracts tend to spend the first half of their time learning to do the work and the second half looking for another job. Moreover, the absence of any prospect of employment after the age of 35 could conceivably deter first class candidates from applying. The research councils hope that with some alteration of pension arrangements, those on short-term appointments will move on to jobs in industry though, outside a few narrow specialties, it is far from certain that this is what industry wants.

PhDs with postdoctoral experience are deemed overqualified for the majority of jobs in industry. Most of the remaining jobs require industrial rather than research council experience. As an indication, over the past 3 years, 230 MRC scientists came to the end of short-term appointments; 13 obtained permanent appointments with MRC and 14 obtained jobs in industry. Most of the remainder went on to yet another short-term appointment. It would be no harm if MRC were permitted to let short-term staff benefit from the pension contributions made on their behalf, rather than to use these contributions, as at present, to subsidize the pensions of other staff members, but it is doubtful if this would fully compensate for such appalling career prospects.

Scientists vote with their feet, and short-term appointments tend to produce few applicants, often of indifferent ability. Permanent appointments attract large numbers of applicants, many of outstanding ability. It has never been explained why it is thought that employing less able scientists on disadvantageous terms will produce greater flexibility and effeetiveness than employing more able scientists on advantageous terms. Perhaps the only moral is that the research councils are capable of mismanaging their affairs quite badly enough without the assistance of Whitehall.

Embryo research

SIR — In the controversy over the status of the human embryo, there exists a state of doubt: some say it is a human being, others say it is not. The views seem fairly equally balanced.

In this impasse, the next step is to examine the consequences should one side or the other eventually be proved to be indisputably correct. On the one side we risk losing a valuable research opportunity — on the other we risk committing murder.

Observational plate tectonics

The latest report of the international radio-interferometric survey IRIS suggests that the direct measurement of plate movements lies just ahead.

THE exciting prospect that radioastronomers will be able, by the use of long-baseline interferometers, directly to measure the motion of tectonic plates, will be a little delayed, it seems. That is one cautious reading of the latest report on four years of work with the international network of geodetic observing stations operated under the title IRIS (for International Radio Interferometric Surveying), which is itself an outgrowth of the combined operation of the US project POLARIS (for Polar Motion Analysis by Radio Interferometric Surveying) and the West German geodetic radio telescope at Wettzell, Bavaria. In an account of observations to the end of November 1984, W.E.Carter, D.S.Robertson and J.R.MacKay of the US National Geodetic Survey (*J.geophys.Res.* **90**, 4577–4587; 1985) quote estimates of the rate at which two baselines are changing, but with errors that are still too great for comfort.

The idea that radio-interferometry might be used for checking on plate tectonics has been in the air ever since radio telescopes separated by a substantial distance were first used for the accurate measurement of the angular size of distant radio sources, quasars for example. But the technology of very long baseline interferometry (VLBI) is only now good enough, and the network of observatories enough, to bear on plate tectonics.

Schematically, the technique is simple enough. Several telescopes simultaneously observe the same distant radio source, recording their signals on magnetic tape (together with an accurate measure of time, most conveniently provided by a local hydrogen maser). In general, there is a time-lag between the receipt of the same waveform at one station and another which, when multiplied by the velocity of light, will be a simple measure of the separation of the two antennas along the line of sight. But given that the Earth rotates, the time-lag will change systematically with time, and in such a way that it should be possible to infer from the observations not merely the relative geometrical position of the two antennas, their baseline separation included, but also the instantaneous position of the axis about which the Earth is rotating.

Practice is, as always, more difficult. One heartfelt complaint by Carter *et al.* is that the sheer weight of the magnetic tape which has to be assembled at a comparator centre after a day's observation by a handful of stations may amount to several hundred kilograms, "a troublesome constraint limiting the growth of geodetic VLBI". Even so, the planners intend adding to the four core stations (Westford, Massachusetts, the Agassiz station in Texas, Richmond, Florida, and Wettzell) cooperation with the Kashima Observatory in Japan and the Shanghai Observatory on mainland China. Other radio telescopes in the United States and elsewhere join in the network as the opportunity arises; that at Onsala, Sweden, takes part for one day a month.

The most startling result so far seems to be that of the measurement of the Earth's pole position, which has been determined since the beginning of 1984 with an accuracy of 2 milliarc seconds (or 6 cm on the ground). This, at least, is the discrepancy between the VLBI measurements of the pole position and those obtained quite independently from satellite ranging, which confirms the accuracy of both sets of measurements. VLBI measurements every three or five days may be enough to keep track of this polar (Chandler) wobble to within a milliarc second.

For what it is worth, the 1984 observations put the position of the pole on a smooth arc destined to form a near-circle some 16.5 metres in diameter, not very different in amplitude from that measured in the previous year but more than twice as great as the amplitude of the Chandler wobble in the two earlier years. Because the VLBI measurements will be made in any case, and because they can be quickly reduced, they will quickly become the preferred way of tracking the wobble.

The data have also thrown up a wealth of detail about departures of the Earth's rotational speed as given by Universal Time (strictly, UT1). Departures from regularity leading to fluctuations of up to 6 milliseconds occur, with some excursions lasting for several months and others for only a few days. It should be possible to monitor the regularity of UT (or of the Earth's rotational speed) to within 0.1 milliseconds by means of a daily hour-long measurement along a single baseline. That is also a by-product well worth having. Daily monitoring may even make it possible to tell which fluctuations of rotational speed are attributable to what.

Other by-products include some information on the nutation of the Earth's rotation, which reflects displacements between the spinning core of the Earth and the outer solid hollow sphere. The Earth tides responsible for the rhythmic fluctuation of the altitude of the radio telescopes in the network are also evident in the data.

So what is there to be said about the baselines and their variation? It is obviously easier to extract from the measurements of the time-lags and their variation with time the quantities whose time-dependence takes a predictable form. This is one reason why fluctuations of the Earth's rotational speed can be monitored so easily; the time-lag between any pair of stations in the VLBI network will be a sinusoidal function of time whose frequency is that of the Earth's rotation.

By contrast, the baseline lengths appear as factors in the constants by which these variable quantities are multiplied, so that the accuracy with which they can be determined is no greater than that of the observations as a whole. Even so, baseline measurements are said to be repeatable to within about one part in 100 million, a mere centimetre or so of error for the longest baselines, for the time being those based in Europe and the United States.

This is the promise for plate tectonics. Many of the movements expected should be readily verified as further measurements of the baselines accumulate. Indeed, Carter *et al.* tantalize their readers with an estimate of the rate of change of the baseline between Westford (Massachusetts) and Onsala (Sweden) and that between Westford and the Texas station. The conclusion is that the trans-atlantic baseline is lengthening by 14 mm a year (with an estimated uncertainty of 3 mm) and that the baseline between Westford and the Texas station is shrinking by 8 mm a year (with an uncertainty of 1 mm).

The sense of these results, at least, is consistent with what plate tectonics would predict; the contraction of the US baseline, for example, is thought to be a consequence of compressional stress on the American plate at least in the region between the Appalachians and the Rockies (see D. I. Gough *et al. Nature* **305**, 619–621; 1983). The fly in the ointment is the suggestion of seasonal errors in the baseline measurements, implying a need for some refinement of the corrections for transmission through the ionosphere and atmosphere. The general interest now will be to see how quickly the VLBI collaboration will be able to accumulate further data. Another year's observations should make all the difference. **John Maddox**

Meteorites

Earthward bound from chaotic regions of the asteroid belt

from Carl D. Murray

It is easy to accept that meteorites, those occasional stones that fall from the sky, are composed of asteriodal material that has been delivered to the Earth. The problem has always been to demonstrate how, subject to some severe observational constraints, even a single fragment in an asteroid-type orbit can eventually cross the path of the Earth. On page 731 of this issue, Jack Wisdom of the Massachusetts Institute of Technology, guided by known locations of chaotic regions in the phase space at one particular place in the asteroid belt, describes a trajectory that can evolve from a fairly typical low-eccentricity orbit to the high eccentricity necessary to achieve the elusive Earth-crossing orbit.

While there are suggestions of a lunar or even martian origin for some of the meteoritic material that has been examined, photometric analysis of most meteorites strongly supports an asteroidal origin. Meteorites are typically thought to be fragments arising from a minor collision between two asteroids. (The asteroid belt is continually evolving because of collisions, which have average encounter velocities of 5 km s^{-1}). The fragments, which will have slightly different orbital parameters from their parent bodies, eventually enter Earth-crossing orbits.

Although the details of this final process are not known, we have some idea of how long it takes. Any fragment that was initially buried more than a few metres inside its parent body will have been shielded from the effects of cosmic rays up to the moment of impact. From chemical studies of meteoritic samples, it has been possible to calculate for how long they have been exposed to cosmic rays and so when the collision which generated them occurred. The exposure ages are generally around 10^7 years for the common stony meteorites, putting severe time constraints on any delivery mechanism.

Regions of the Solar System that might be expected to act as a source for meteorites fall near the low-order orbital resonances of Jupiter. An asteroid occupying the 2/1 resonance, for example, orbits the sun in half the orbital period of Jupiter. Thus, over successive orbits the asteroid will experience a repeated and cumulative gravitational perturbation from Jupiter that could tend to remove it to a different orbit. Prominent gaps (Kirkwood gaps) in the asteroid belt occur at such resonances and Wisdom has already demonstrated[2] how the 3/1 resonance can be cleared of asteroids. He showed the existence of a large chaotic region of the phase space (defined by positions and velocities) in the vicinity of the resonance. In such a chaotic region an asteroid could experience large and essentially random changes in its orbital parameters, with the final orbit being sensitively dependent on the initial conditions. The key point is that the equations of motion are non-linear and the resulting deterministic chaos is now being recognized as a common feature of non-linear equations for certain sets of starting conditions. The most critical orbital parameter for the asteroid's survival is its eccentricity. A value larger than about 0.3 implies that it will cross Mars. Having shown how such eccentricities could be achieved in the chaotic zone, Wisdom invoked Mars as the final remover of material, whether by impact or scattering. It seemed natural, therefore, to use knowledge of the locations of the chaotic regions as a starting point in a search for regions that could produce Earth-crossing material.

In a paper presented to the Meteoritical Society last summer, George Wetherill of the Carnegie Institution in Washington DC, claimed that the observed influx of the ordinary chrondrite meteorites could be accounted for only by gravitationally accelerated material from a region in the vicinity of the 3/1 resonance[3]. Wisdom has now provided details of such a mechanism using the known locations of the chaotic regions as a basis for finding Earth-crossing trajectories. When he integrated different sets of starting conditions, at the fifth attempt he found a trajectory which became Earth-crossing. The equations he integrated have sufficient degrees of freedom for Arnol'd diffusion to occur — whereby an orbit, given enough time, can eventually 'leak' into different regions of the phase space[4]. (Arnol'd diffusion has yet to be identified in any Solar System integration since the timescales involved are almost certainly greater than the age of the Solar System.) Wisdom's result is that the orbit evolves from low to high eccentricity within a few hundred thousand years, thereby satisfying the cosmic-ray exposure age constraint. The beauty of the mechanism is that it does not involve any complicated procedures that require more than one close approach to another planet.

The 3/1 resonance does not have a monopoly on chaotic regions — the boundaries of all resonances are chaotic, the extent of the chaos depending of such factors as Jupiter's eccentricity and the strength of the resonance. In the past, celestial mechanicians have devoted much effort to the study of the prominent first-order resonances in the asteroid belt, trying to explain such features as the 2/1 Hecuba gap and the 3/2 Hilda group of asteroids. It now seems that an understanding of the dynamics of the innocuous 3/1 resonance will provide answers to some of the most fundamental problems of Solar System dynamics. □

Avian ecology

Mass mortality in Pacific seabirds

from Jared M. Diamond

What is the evolutionary importance of rare events? Does natural selection proceed constantly, or are its effects concentrated during episodes of widespread mortality? R. and E. A. Schreiber (*Science* **225**, 713; 1984) address this question for some of the world's longest-lived vertebrates, victims of a recent catastrophe.

El Niño Southern Oscillations (ENSOs) are recurrent, widespread climatic events involving major warming of the whole eastern tropical Pacific Ocean. The most recent ENSO, in 1982–83, was the most severe yet recorded. At the site of the Schreibers' study — the low atoll of Christmas Island in the central Pacific —annual rainfall, normally 30 inches, reached 156 inches in the year beginning July 1982, including 16 inches in one day. Among the consequences were extensive flooding of the island, a drop in oceanic primary productivity of phytoplankton dependent on cold surface waters, and hence depleted stocks of fish and squid ultimately dependent on that primary production. Eight million seabirds of the eighteen species that breed on Christmas Island feed on those fish and squid. Although most temperate zone song-birds breed in their second year, lay 3 – 10 eggs and have life expectancies of a few years, tropical seabirds typically have a single large egg with a long incubation time, long periods of juvenile dependency on parents, late onset of breeding and very long lives. Long-term studies of Christmas Island seabirds have revealed many details of their leisurely life cycles. Some

species have lifespans of 50 – 70 years, more than the lifetime of the rings used to tag them. The tropic birds breed only after the age of 5 years, live at least 35 years and form permanent pairs. A young frigate bird is fed for about one and a half years by its mother (the father leaves after 1 month, probably to nest with another female). Fledged sooty terns fly to sea, do not alight for 9 years (presumably sleeping in flight), then infallibly return to their natal island, where they court on the wing, finally alight to copulate, and lay the egg on the next day.

From 1940 to June 1982, a period that included seven ENSOs, there was no recorded instance of total reproductive failure for any seabird species at Christmas Island. During the Schreibers' June 1982 visit, just before the onset of the ENSO, seabird populations were still normal. But by November 1982 there was total reproductive failure for all species. At that time five species (including the two that are usually most abundant) were completely absent, while the remaining species were represented by few adults, with no nests or else nests with dead, underweight or starving chicks. Nests in ground burrows were flooded, many tree nests had been washed out and young in surviving nests starved.

What happened to the millions of adult birds that should have been breeding then on Christmas Island? Did they, too, die, or did they simply go elsewhere until conditions improved? The Schreibers found almost no skeletons of adults on the island, yet bird numbers were still far below normal in October 1983. It is thought that 90 per cent of the breeding seabirds, including those present and attempting to breed in July 1982, died at sea from starvation.

The low reproductive potential of tropical seabirds suggests that it will be years before the breeding colonies of Christmas Island have recovered to their former numbers. Thus, a large-scale natural experiment in fluctuating selection is underway. Intraspecific competition will be relaxed for a long time: how will this affect reproductive effort and individual variation in morphology? Was the mortality in 1982 indiscriminate and total, as presently assumed, or did a few of the fittest survive? These long-lived birds must experience many 'normal' ENSOs in their lifetimes, and a severe one every couple of generations; could there be features of the life histories of the birds that have arisen as adaptations to these rare events? The answers to these questions may emerge from the long-term studies on Christmas Island. □

Meteorology

Clouds and climate regulation

from Richard C. J. Somerville

THE role of clouds in regulating climate is still largely a mystery, and the treatment of clouds in conventional climate models may be seriously inadequate. If cloud effects are as strong as some recent research suggests, considerable uncertainty must characterize the results of even the most advanced present-day models of climate. Predictions of the climate changes resulting from burning fossil fuels, which adds CO_2 to the atmosphere, for example, depend strongly on how clouds are modelled; clouds may tend to amplify changes, or they may act as a giant global thermostat, helping to stabilize the climate.

The potentially large influence of clouds on climate arises from their effects on the transfer through the atmosphere of both incoming solar and outgoing terrestrial radiation. That clouds may dramatically affect surface temperature by both these mechanisms is a matter of everyday experience. Daytime maximum temperatures are substantially lower on cloudy days than on fair ones, and cloudless nights are cooler than overcast ones, other factors being equal. These commonplace examples illustrate the two major influences of clouds on the planetary radiation budget: clouds can alter both the planetary albedo, or reflectivity, and the greenhouse effect, by helping to trap radiation which otherwise would be lost into space.

The average albedo of our planet is about 30 per cent, so only 70 per cent of incident solar radiation is actually available to power the climate system. Clouds cover nearly half the surface of the Earth but account for about two-thirds of the planetary albedo[1]. We do not know whether the albedo or cloud cover were markedly different during, say, the last ice age. In fact, we have no good explanation of the present-day values of these fundamental climatic parameters. It is perhaps even more disquieting that we cannot reliably predict whether or how these parameters are likely to change over the next century, as the concentration of atmospheric CO_2 approaches twice its pre-industrial value. It has recently been estimated, for example, that the temperature increase due to the greenhouse effect produced by doubling CO_2 might be completely offset if the amount of low-altitude cloudiness were to increase simultaneously by 10 per cent[2]. This result emerges from a mathematical model sensitivity study, essentially a calculation of the climatic response to an assumed change in cloudiness.

The predicament of climate theorists is that it is relatively easy to demonstrate that climate is potentially sensitive to clouds — as in the example above — but very difficult to model clouds realistically. Climate models incorporate powerful radiative transfer algorithms that could calculate atmospheric heating and cooling extremely accurately, if only the distribution of all the radiatively active constituents in the atmosphere were known precisely[3]. Two of the most important such constituents, however, are water vapour and cloud, both notoriously changeable and difficult to predict. Idealized mathematical models have been developed to simulate many of the physical mechanisms through which a change in climate might alter clouds, which can then in turn feed back on climate change through their radiative effects[4,5]. Not even the most advanced of climate models, however, simulate all aspects of the present-day global distribution of cloudiness well enough to inspire confidence in cloud forecasts for climates differing significantly from our present one[6].

Many sensitivity studies have shown that climate can be affected strongly by changes in cloud height as well as changes in cloud amount[7]. Recent research has raised the additional possibility that increased atmospheric pollution might alter cloud optical properties enough to influence the global albedo substantially[8]. Another mechanism which might produce a similiar effect is the possible dependence of cloud liquid water content on temperature[9]. In the context of the CO_2 climate problem, both these processes are candidate cooling mechanisms that might at least partially compensate for the warming resulting from the enhanced greenhouse effect. The quantitive importance of these processes is still uncertain, but they illustrate the real possibility that

the effect on climate of feedback from cloud radiation may be significant even in the absence of changes in cloud amount or height.

One important reason for the frustratingly slow progress in this field has been the lack of adequate global cloud observations. Satellite remote sensing has only recently begun to fulfill its considerable promise in this area[9-11]. Parameters that can now be measured with useful precision include cloud amounts, cloud heights, cloud-top temperatures and some optical properties of clouds. Earth radiation budget parameters, such as albedo and outgoing longwave radiation, are now also being monitored by satellites. Although no dramatic breakthroughs seem likely, these data will be invaluable in the gradual development and verification of improved climate models.

For those who are unwilling to wait a century or so to learn whether CO_2 doubling will or will not have its predicted climatic consequences, there may be a quicker payoff from research on cloud-radiation feedbacks. Numerical weather prediction models, on which routine operational meteorological forecasts are based, have become so complex that they are now almost indistinguishable from comprehensive climate models, but the conventional wisdom has long been that short-range atmospheric circulation forecasts, for a day or so in advance, are relatively insensitive to radiative processes. Indeed, such processes were until recently highly simplified or even entirely neglected in the forecast models used by national weather services. As the duration of the predictions increases, however, such cavalier physical simplifications become less justifiable. There is now considerable evidence that a one-week forecast may benefit significantly from more realistic treatments of cloud-radiation interaction[12,13], and improvements in modelling clouds and their effects are likely to increase gradually the competence of an already skilful enterprise. If research on modelling cloud effects can lead to real improvements in one-week forecasts, the benefits to many weather-sensitive sectors of the economy should be substantial.

It is climate theory rather than numerical weather prediction, however, that stands to gain the most from any real advances in our understanding of cloud-radiation feedbacks. It is already clear from sensitivity studies that cloud feedbacks could plausibly either double or halve the typical estimated surface temperature change resulting from increased concentrations of atmospheric CO_2. But our present ignorance of these feedbacks is so great that we cannot even be certain whether the net effect of all the cloud processes is a positive or a negative feedback. □

Developmental neurobiology

Laminin for axonal guidance?

from Joshua R. Sanes

INTERACTION of neuronal processes with the surfaces on which they grow has been a subject of increasing interest to developmental neurobiologists. *In vitro*, it is clear that adhesion of growing processes, or neurites, to substrates is an important determinant of neurite elongation[1] and that material deposited by non-neural cells can promote and direct neurite extension[2]. *In vivo*, regenerating peripheral axons frequently grow along basal laminae to reach and reinnervate their targets[3]. These two observations have now been brought together in a satisfying way by the demonstration that laminin[4,5], a structural component of adult basal laminae[6], is a major factor promoting neurite outgrowth that is secreted by cultured cells.

In 1978, Collins[7] demonstrated that proteins secreted by heart cells promote neurite outgrowth in a way that distinguishes them from soluble 'trophic' factors such as nerve growth factor (NGF): they bind to the culture dish and seem to act by increasing the adhesion of neurite to substrate. Many cell types have since been shown to secrete such material[7] and efforts are now being made to characterize the responsible factor. These have proceeded along two lines. First, the outgrowth-promoting activities have been purified from medium conditioned by non-neural cells, using neurite outgrowth as an assay. Second, based on the finding that many proteins secreted *in vitro* are components of extracellular matrices *in vivo*, the effects of purified extracellular matrix molecules on neurite outgrowth have been assessed and compared to those of outgrowth-promoting factors. Although several such molecules turn out to be effective substrates for neurite outgrowth, most attention has focussed on laminin, a glycoprotein that is present in virtually all basal laminae and that had already been shown to promote attachment of epithelial cells to collagenous substrates[6]. When tested for neurite outgrowth-promoting activity, laminin seemed to be the most effective of the molecules examined, to affect the widest variety of neuronal types and to be remarkably similar in its effects to the outgrowth-promoting factors secreted by cultured cells[8-13].

As these results accumulated, it became logical to suppose that the secreted outgrowth-promoting activity might actually be laminin, but two observations suggested that it was not. First, antisera to laminin that blocked neurite outgrowth on laminin-coated dishes did not inhibit outgrowth on substrates coated with conditioned medium[4,9,11]. Second, Lander *et al.* found that the factor from conditioned medium contains a heparan sulphate proteoglycan, although they appreciated that the proteoglycan was not necessarily the molecule that the axons recognized[14]. The parallels between laminin and this factor were, however, sufficiently striking to be pursued, and now Lander *et al.*[4] and Davis *et al.*[5] have obtained new evidence indicating that laminin is indeed responsible for the outgrowth-promoting activity in a variety of conditioned media. Laminin co-purifies with the outgrowth-promoting activity through several fractionation steps; it is a major component of the purest factor obtained; antiserum to laminin precipitates outgrowth-promoting activity from conditioned medium; and sufficient laminin is present in conditioned medium to account for outgrowth-promoting activity. The laminin is likely to be complexed with the heparan sulphate proteoglycan previously described[14], because anti-laminin precipitates both molecules from medium. Furthermore, while heparan sulphate proteoglycan alone does not stimulate neurite outgrowth[9], a monoclonal antibody that blocks the outgrowth-promoting activity of conditioned medium[15] recognizes a complex of laminin with proteoglycan (W. Matthew, personal communication).

The failure of anti-laminin to block the activity of the complex remains unexplained and provocative. The laminin molecules in the complex may differ in their primary structure, glycosylation or conformation from the laminin used to generate the serum, or the active site of the complexed laminin might be inaccessible to antibody. It seems odd that the active site of the laminin could be accessible to an axon but inaccessible to an antibody; one interesting possibility is that heparan sulphate on a neuronal mem-

brane could displace heparan sulphate in the complex, giving the axon special access to an active site. In any event, these results argue for caution in interpreting experiments designed to identify active molecules by immunological blockade.

The findings that laminin promotes neurite outgrowth and is a major component of the outgrowth-promoting factor secreted by several types of cells have several implications for research on axonal growth and guidance. First, neurites can be predicted to bear laminin-receptors[6] on their membranes, so it becomes important to identify and characterize these molecules. Second, we will want to learn if and where laminin guides neurite outgrowth *in vivo*. Although the immunochemical difficulties I have already discussed may render interpretation of antibody-blocking experiments difficult, it should be possible to learn how far outgrowth on basal laminae depends on laminin as opposed to other extracellular matrix molecules such as fibronectin and collagen, which also promote neurite outgrowth *in vitro*[8,10,16,17] Since in the embryo central axons grow along basal laminae to reach their targets[18], guidance by laminin may be relevant to the growth of central as well as peripheral axons. Finally, the clinically disastrous failure of mammalian central axons to regenerate following injury is now suspected to be caused, at least in part, by a deficiency in their environment, because they can grow long distances through grafts of peripheral nerve segments rich in basal lamina[19]. Intriguingly, fish optic nerves, which have an unusual ability to regenerate, have very recently been found to accumulate high levels of laminin after injury[11] Could laminin be one of the factors whose absence impedes regeneration in our brains and spinal cords? □

Astrophysics

Optical bursts – where are they?

from K. Hurley

DESPITE their brevity, and sometimes because of it, transient events are often the most spectacular in astrophysics. Gamma-ray bursters[1], now widely believed to occur on or about neutron stars, are one example; typically they produce a blast of radiation lasting several seconds and with a peak luminosity of at least nine orders of magnitude over the quiescent state, in which they are quite undetectable. Transient phenomena in the optical waveband, apparently associated with some bursters[2,3] have also been detected but, until recently, only on archival photographic plates. Therefore, they were not time-resolved. Now that continuous monitoring of optical bursts is being undertaken, the evidence indicates that they have light curves which strongly resemble their progenitor gamma bursts, and a clever argument has been advanced which uses this fact to constrain the still unknown distances to bursters.

Our present understanding of the gamma-burst phenomenon is still quite incomplete. It is much easier to list the objects with which gamma bursters are not associated, such as steady X-ray and γ-ray sources, than it is to identify convincingly any quiescent counterpart to them. This has proven to be perhaps the major obstacle to progress, as it leaves the distance to the source uncertain by four orders of magnitude. So, although a wealth of circumstantial evidence points to strongly magnetized neutron stars as burst sources in at least some cases, the question of the type of stellar system — if any — in which the neutron star resides has still not been answered.

Perhaps nowhere has the problem been so acute as with the fascinating burster of 5 March 1979[4]: not only was its peak intensity (at Earth) the largest recorded for a gamma burst, but also its localization coincides with the N49 supernova remnant in the Large Magellanic Cloud (LMC), at a distance of 55 kiloparsecs. A straightforward interpretation would be that the burst originated on the neutron star which produced the remnant. But a number of objections can be raised to this idea, not least that, if the source radiated isotropically from the LMC, then for a brief instant it outshone (in γ-rays alone) the entire luminous output of our Galaxy. A tantalizing new piece of evidence was announced last summer at a meeting at Stanford University and subsequently in *Nature*[5] During a five-month period of optical monitoring of the 5 March source, three optical bursts were detected and clearly time-resolved. Their light curves generally resembled the time histories of gamma bursts, although no simultaneous γ-ray activity was noted at the times of the optical bursts (the instruments in orbit at the time were probably not sensitive enough to record it). Thus, the relation between the 5 March gamma bursts and the optical bursts remains tentative. However, as R. London of Lawrence Livermore Laboratory was quick to point out, if the two bursts are associated, the distance to the source is strongly constrained, an idea later confirmed by J.-M. Hameury, J. P. Lasota and S. Bonnazola of Meudon Observatory.

The argument is that if the optical radiation is due to a thermal mechanism (for example, reprocessing of gamma radiation[6] in an accretion disk or in the atmosphere of a stellar companion), the luminosity of the mechanism cannot exceed that of black-body radiation. Then, since the dimension of the optical source cannot exceed ct, where c is the speed of light and t is the rise time of the optical flash, a relation is obtained between the maximum distance to the source and its temperature. That temperature turns out to be at least several million electron volts for a source in the LMC. In general, it is difficult to construct thermal models with these temperatures and furthermore, the 5 March burster has never been observed to emit at these energies. The conclusion is that its source is much nearer than the LMC. In arriving at this conclusion, a number of special models for the optical radiation have to be excluded: coherent emission, sources in relativistic expansion, beaming and special geometries that appear to violate causality.

In addition to providing distance constraints, time-resolved optical flashes may do for γ-ray bursters what they did for X-ray bursters[7], that is, allow an estimate of the dimension of the reprocessing region (via both the rise time and the duration of the flash). In the 5 March case, for example, a reprocessing region with a typical dimension of 30,000 km is indicated, ruling out reprocessing in the atmosphere of a non-degenerate stellar companion and suggesting the possibility of an accretion disk.

But what of the tentative nature of the association between optical flashes and gamma bursts? There has never been any simultaneous observation of the two, and since optical instruments tend to be many orders of magnitude more sensitive (as energy-flux detectors) than γ-ray burst instruments, for the time being only optical flashes associated with the largest (relatively infrequent) gamma bursts can be expected to give rise to coincident detections. Simultaneous direct imaging and photometry of an optical flash should

soon be possible with a unique system now being deployed at the European Southern Observatory. The experiment, being conducted by H. Pedersen, consists of a battery of small automated telescopes each trained on the position of a particular γ-ray burst source.

Much of the uncertainty surrounding optical flashes comes from the possibility that they are generated rather closer to home, for example by meteors in the upper atmosphere. The use of two detection systems separated by even one kilometre eliminates these effects by parallax. Such a study was recently undertaken on an intercontinental baseline[8] and another two-telescope proposal is under consideration by the European Southern Observatory. On top of this, a novel electronic camera array being installed at Kitt Peak National Observatory[9,10], will eventually provide permanent night-time mon-itoring of much of the sky for optical transients down to magnitude 11, with source localization at the arc-second level. It is expected that some twenty optical flashes associated with gamma bursts will be detected per year (not to mention a host of other short-timescale astronomical events), dramatically increasing the probability of a simultaneous optical and gamma-ray detection. This set up will also greatly increase accuracy of localization, in the wake of which may come both the long-awaited identification of the counterpart and the answer to the question of the distance scale. □

Laser physics

Trapping cooled sodium atoms

from B. W. Petley

SPECTROSCOPISTS have long dreamed of being able to make measurements on atoms or ions which are essentially at rest, and even on single atoms in that condition. For if they could do so, the study of fine detail of atomic transistions would no longer be impeded by the broadening of spectral lines as a consequence of the Doppler effect, or by the fact that, in work with beams of atoms and ions, the accuracy of observations is limited by the time spent by individual atoms and molecules within the action region of the apparatus. One practical consequence could be the further refinement of the accuracy of atomic frequency standards.

With the recent publication of techniques for using lasers to 'cool' atoms, or to rob them of translational velocity, and with the availability of electromagnetic traps for small numbers of atoms, the dream seemed about to come true. Now, Alan L. Migdall, John V. Prodan and Bill D. Phillips of the Gaithersburg laboratories of the National Bureau of Standards, together with Thomas H. Bergeman and Harold J. Metcalf of the State University of New York, Stony Brook, have reported the trapping of laser-cooled sodium atoms. The results were presented at the spring meeting of the American Physical Society on 24 April 1985 and have just been published (*Phys. Rev. Lett.* **54**, 2596; 1985). Other groups are rumoured to be close to success as well. Thus, Metcalf (see opposite) reports that A. Ashkin and his colleagues have extended their laser trapping techniques from 10 mm oil droplets to sodium atoms. We can expect a lively conference season in the months ahead.

The first-order Doppler effect, which is proportional to v/c for individual atoms and for a source in thermal equilibrium, usually results in a broadening of spectral lines by a few GHz (or about 0.1 cm^{-1}). The use of tuneable dye lasers in conjunction with atomic and ion beams has for some time made it possible to observe only those atoms that are travelling perpendicular to the line of sight, which for practical purposes removes the first-order Doppler broadening. For many purposes, however, the second-order (relativistic) effect, proportional to $(v/c)^2$, remains an impediment to accurate measurements.

The laser cooling techniques recently reported follow earlier suggestions by Letokhov and others in Moscow, by Schawlow and Hansch at Stanford and by Wineland and Dehmelt. A beam of atoms is decelerated by absorbing a counter-propagating beam of laser light. The objective is to cool such beams to milli-Kelvin (mK) temperatures. The trade-off with laser cooling is that, as atoms are slowed by absorbing N counter-propagating photons in the beam direction, they are heated in the transverse direction by the isotropically re-emitted photons as $N^{1/2}$, which may amount to 50 mK for 20,000 photons. As the atoms have an energy spread, it is convenient to express this as a 'temperature'.

Although laser cooling had already been demonstrated by groups in Moscow, Washington and elsewhere, optical pumping effects, which deplete the proportion of the atoms in the state absorbing the counter-propagating radiation, had hindered the achievement of the desired mK temperatures. Each time, for example, that a sodium atom absorbs a 589 nm photon its velocity is slowed by about 3 cm s^{-1}, but optical pumping effects and Doppler shifts that occur after the absorption and isotropic re-emission of about a hundred photons, limit the velocity reduction to about 3 m s^{-1}, which is a long way short of the reduction by about 600 m s^{-1} required to bring the atoms to rest.

By overcoming these optical pumping effects, two groups have successfully cooled atoms to mK temperatures. Both used sodium atoms, whose 589-nm transition is so conveniently accessible with the rhodamine-6G laser dye, and both used the same transition (Fig. 1) using the indicated σ^+ line to slow the atoms. Diverging beams of atoms were cooled by a counter-propagating laser beam which converged at the same angle (3 mrad) onto the source. For this transition, the optical pumping effect results from the decay from an upper level into the F=1 ground state. In addition to avoiding populating such levels, the frequency of the incident radiation must also track the changing Doppler shift during the absorption of the 20,000 or so photons required to bring the atom to rest. Where the two groups differ is that one changed the frequency of the laser and the other the frequency of the atomic transition as the atoms are slowed.

W. Ertmer *et al.* (*Phys. Rev. Lett.* **54**, 996; 1985) swept the laser frequency using an acousto-electro-optic travelling wave modulator and added a further weak modulation 1,772 mHz side-band to pump any atoms which reach the 3S(F=1) state back up to the 3S(F=2) state. This produces a pulse of cooled atoms. On the other hand, J. Prodan *et al.* (*Phys. Rev. Lett.* **54**, 992; 1985) tuned the transition frequency by passing the atomic beam through the magnetic field produced by a tapered solenoid. The magnetic field and light polarization exploited the Zeeman effect to avoid the optical pumping. Deceleration was a two-stage process; the atoms were slowed to a low velocity in the solenoid and then drifted a further 0.4 m into the observation region where they

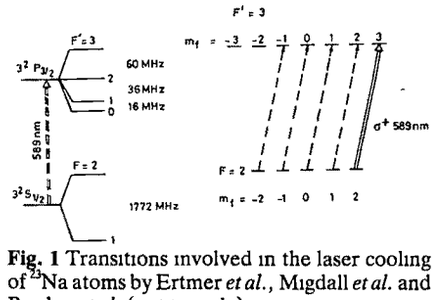

Fig. 1 Transitions involved in the laser cooling of ^{23}Na atoms by Ertmer *et al.*, Migdall *et al.* and Prodan *et al.* (not to scale).

received a further 0.1 to 0.4 ms pulse of cooling laser radiation. The method produces position-dependent cooling. With a strongly saturated transition, the atoms will spend about a half of their time in the upper energy state, radiating at a rate governed by their natural lifetime of about 16 ns. Thus their maximum deceleration would be about 10^6 m s^{-2}, which means that a sodium beam could be stopped in about 1 ms, after travelling a distance of about 0.5 m. The deceleration achieved by Prodan *et al.* was about half maximum.

The temperatures of the cooled atoms were monitored by the fluorescence produced by a weak laser beam crossing the atomic beam at a convenient angle. Ertmer *et al.* estimate that some 10^6 atoms per ml could be cooled to a velocity distribution whose width corresponds to a temperature of 50 mK (25 MHz half-width). The corresponding velocity spread obtained by Prodan *et al.* was equivalent to about 100 mK with a density of about 10^5 atoms per ml. For their subsequent successful trapping of some of their cooled atoms, Prodan and his colleagues used a trap comprised of two opposed coils (reminiscent of an opposed Helmholtz pair); the downstream coil is energized once the atoms have drifted into the trap. The coils produce a field gradient of about 1 T m^{-1}, which reflects and traps atoms with an axial temperature of below 17 mK. The upstream coil provides a gradient field which is used in the final stage of laser coding once the atoms have entered the trapping region. The atoms then spread out to fill the 20 ml volume of the trap and some 10^4 atoms are trapped for about 0.83 s (the decay time). The next stage will be to attempt to use optical trappings to cool the atoms even further so that they are sufficiently at rest to dispense with the trap. Meantime many exciting experiments are in prospect.

Atomic frequency standards

To appreciate the possibilities of the new technique one has only to consider a paper of J. J. Bollinger *et al.* (*Phys. Rev. Lett.* **54**, 1000; 1985) in which the successful operation of an atomic frequency standard based on laser cooled ions is reported. Bollinger *et al.* trapped $^9Be^+$ ions in a Penning trap, whereby the ions were confined axially by a hyperbolic electrostatic potential distribution, and radially by the combined action of the electrostatic and magnetic fields. The ion motion comprised the cyclotron motion about the magnetic flux axis and the circular ($E \times B$) drift (or magnetron motion) each in the radial plane, together with the axial motion. Each may have a temperature associated with it. In the experiment described, the cyclotron and axial temperatures were less than 100 mK and the magnetron temperature less than 2 K (with the cooling laser on continuously). Some 2,000 ions were confined for many hours in the trap, with ion cloud diameters of 0.3 to 0.5 mm. The laser radiation was directed along the axis of the field and tuned to be slightly on the low frequency side of the absorption. The radiation not only cooled the axial motion but also coupled with the magnetron motion, and so could be used to compress (cool) the ion orbit.

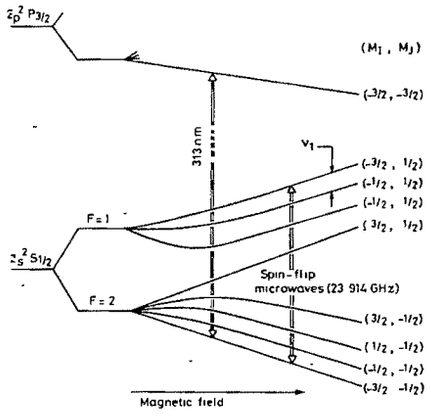

Fig. 2 The Zeeman splitting in a magnetic field, and the hyperfine structure of $^9Be^+$ showing the transition used for laser cooling by Bollinger *et al* (not to scale)

Bollinger *et al.* report a measurement of the hyperfine ground-state transition frequency ν_1, at its magnetic-field independent point (0.8149 T), of 303 MHz with an estimated standard deviation uncertainty of only 57 μHz (see Fig. 2). The experiment involved triple resonance, requiring first, 20 μW of 313 nm radiation to excite the 2S-2P optical transition; next 23.9 GHz microwaves to excite the indicated electron spin-flip transition; and finally, radio-frequency radiation to excite the transition ν_1. The last was provided by a frequency synthesizer which was referenced to a hydrogen maser. The microwave radiation served to make the rate of excitation of the optical transition (and hence the observed fluorescence) sensitive to the upper level of the state pumped by the ν_1 line.

To excite and interrogate the ν_1 transition, a 0.5–2 s pulse of 303 MHz radiation was followed by a second 303 MHz pulse, 10 or 19 s later. This leads to a resonance some 25 mHz wide. It was only necessary to change the radiofrequency by millihertz steps over a 0.1 Hz range in order to scan the resonance. The optical and microwave signals were applied for 3 s before the first

Optically trapped oil droplets

In a recent article in *Physical Review Letters*[1], A. Ashkin and J. Dziedzic of AT&T Bell Laboratories report the first stable trapping and manipulation of single minuscule oil droplets using only the forces derived from the pressure of laser light. Although the force exerted by light on any object is normally so tiny that it is not of importance, the special circumstances contrived by the experimenters make it the dominant force. The techniques have a wide range of potential applications.

The new aspect of the work derives from the fact that the light beams are alternating rather than constant. Recent interest in optical trapping of free neutral atoms has produced an optical Earnshaw theorem[2] showing that steady radiation pressure traps cannot produce stable confinement, just as in the case of steady electrical fields and charged particles. However, just as ion traps can work very well with alternating fields, optical traps can work very well with alternating beams. Using an arrangement of mirrors and shutters to produce the appropriate beams, Ashkin and Dziedzic have confined and manipulated oil droplets of only 0.001 cm diameter for up to five hours. This was accomplished in the air, at atmospheric pressure, with no physical contact with the drop and no observable deterioration by heating.

Arthur Ashkin has been thinking about particle and atom trapping for a long time. In 1970, in his first paper on the subject[3], he laid out the fundamental principles and suggested a number of applications. The attractive features of his technique for manipulating micron sized particles particles are the lack of physical contact, complete control over motion and the lack of heating or disturbance by radiometric forces. The earliest experiments suggested the possibility of separation of particles by size or composition, as well as showing how to transport, levitate and handle them. Later in that same year, Ashkin described the possible application of these ideas to free neutral atoms[4], a subject of much interest in recent years (reviewed in ref. 5).

Ashkin and colleagues have also succeeded in detaining free sodium atoms in a configuration of laser beams that produces viscous optical forces (S. Chu, personal communication). Our own group has recently accomplished the first real trapping of neutral atoms by confining laser-cooled sodium in a magnetic trap for more than 1 s (see accompanying article[6]).

Whereas it is clear that a new field of applied physics, involving the optical manipulation of free neutral atoms, micron size particles and other tiny objects, is being born, we cannot yet foresee the complete range of its applications. They will include materials processing, information storage, precision atomic spectroscopy, studies in classical mechanics and chaos, isotope separation, control of chemical reactions and manipulation of single cells or even macromolecules. Surely there will be many others.

Harold Metcalf

6 Petley, B W *Nature News and Views* **315**, 716 (1985)

pulse and after the second pulse, serving as state-preparation and state-sensing pulses, respectively.

Despite the cooling, the second-order Doppler-shift correction −107 μHz was still important. It arose from the heating of the ion cyclotron and axial motions to about 3 K during the 10 to 19 s that the laser was switched off and is probably due to small imperfections in the construction of the trap. It was also necessary to apply a correction of about −6.1 μHz to allow for the rotation of the earth (and ion trap) around the ion cloud.

The same team has gone on to use their apparatus to set 300-fold lower limits on the spatial anisotrophy of inertia by performing a Hughes–Drever type of measurement (Prestage, J. D. *et al. Phys. Rev. Lett.* **54,** 2387; 1985). Their sensitivity was better than 50 μHz to changes in the orientation of their $^{9}Be^{+}$ ions with respect to the Sun and Galaxy (see Gallop, J C. & Petley, B. W. *Nature* **303,** 53; 1983). Various groups have explored certain clock transitions in $^{137}Ba^{+}$, $^{171}Yb^{+}$, $^{199}Hg^{+}$, $^{201}Hg^{+}$ and other ions, to the limits set by commercial caesium beam standards, by using different methods to cool the ions.

Other spectacular measurements with ion traps have been reported. Thus, the fluorescence signal from a single trapped ion has been seen (Neuhauser, R. *et al. Phys Rev* **22,** 1137; 1980) and, recently, Gabrielese, G. *et al.* (*Phys. Rev. Lett.* **54,** 537; 1985) reported an investigation of relativistic hysteresis effects in the cyclotron motion of a single electron that was trapped continuously over a period of ten months. In addition, the Dehmelt and Van Dycke group at Seattle, and others at Mainz and elsewhere, have made high precision measurements of the electron magnetic moment anomaly and the ratio of proton mass to electron mass.

There is no lack of narrow optical lines that could be studied with trapped ions, but all have drawbacks and there are formidable experimental difficulties to be overcome. Thus, Q values in excess of 10^{14} are anticipated for the $^{1}P_{0}-{}^{1}S_{0}$ transition in Tl^{+}, Al^{+} or Ga^{+} as well as in the D←P←S Raman transition in Ba^{+}, the S←D two-photon transition in Hg^{+} or the $^{2}P_{3/2}\leftarrow{}^{2}P_{1/2}$ transition in Pb^{+}. Similarly, many high-Q transitions will be explored with trapped atoms — the 1S→2S transition in atomic hydrogen will be of particular interest. By contrast, the Q value of the current caesium frequency standards is in the region of 10^{9}.

In the shorter term, the highest accuracies will be achieved on the measurements of fine and hyperfine structure transitions that lies at convenient radio and microwave frequencies. For the higher frequencies, the dye-laser technology must be improved to give wider frequency coverage and to use narrower line-widths. Also frequency multiplication into the visible region and beyond will have to be simplified and increased in accuracy.

As the techniques advance, we can expect to gain improved knowledge of atomic and ionic phenomena. One can even contemplate experiments involving new levels of sophistication and accuracy, such as parity conservation, gravitational interactions with atomic energy levels, Hughes–Drever type measurements, measurements of the properties of fundamental particles and, some day, the 1S→2S transition in anti-hydrogen. Moreover, we can expect greatly improved devices that will benefit technology as well as science — better frequency standards will almost certainly be one of the first gains. □

Archaeology

Man as part of the ecosystem

from Henry Cleere

Sir Mortimer Wheeler once described archaeology as a "humanistic science", and in that phrase he neatly encapsulated the confused, almost schizophrenic, view the discipline has of itself — a view, moreover, that is shared by those outside the field. Officially, the matter was resolved more than thirty years ago: government support to the Council for British Archaeology is paid through the British Academy rather than the Royal Society or one of the science research councils.

Whether or not archaeology can lay claim to be a science by virtue of its methodology remains a subject for debate, although it is undeniable that science now has an expanding role to play in archaeology. Of course, this is no recent phenomenon: physical and biological sciences have contributed to the interpretation of archaeological data for many years. Accurate dating of archaeological material since 1945 has used techniques such as radiocarbon analysis, thermoluminescence and dendrochronology. The provenancing of stone, ceramic and metal artefacts has been improved immeasurably by advances such as neutron activation analysis, atomic absorption spectroscopy, electron-probe microanalysis and scanning electron microscopy, recently reviewed in ref. 1.

This, however, is science coming to the aid of archaeology in its more traditional guise — the classification and interpretation of human artefacts. Over the past three decades there has been a significant change in archaeologists' perceptions of the range of materials available to them in their work. In modern excavations it is no longer enough to retrieve and examine artefacts and structures that are the result of direct human intervention: man is now seen as a component of an ecosystem, reacting with that ecosystem as it evolves over time and often profoundly and permanently modifying it to his own advantage. For the excavator it is essential to retrieve a wide spectrum of non-artefactual material from ancient contexts to recreate the environment of a site or of a region. This can help us to clarify the extent to which the environment has influenced the socio-economic development of a human community and how far man has wrought changes on that environment.

The new sub-discipline of 'environmental archaeology' is eclectic in the materials that form its basis. Plant remains may be macroscopic (from tree trunks to seeds) or microscopic (fossil pollen, phytoliths and diatoms). The presence or absence of pollens from the weeds of cultivation in the pollen diagram from a site can provide socio-economic information about a human community that artefactual assemblages may merely hint at or not represent at all. Palaeozoology embraces mammalian (and human) remains, fish and bird bones, insects of all kinds and molluscs, particularly land snails. Certain species of insects and land snails are highly stenotopic (adapted to a narrow range of habitats) and so their identification in an assemblage from an excavation can supply much specific information about a site and its environment. The correct identification of soils and sediments on and around early settlements provides important climatic and geomorphological date that can be crucial to the interpretation of a site and its community.

Several general studies on environmental archaeology have recently been published[2-7]. Some excavations have been carried out with the recovery of environmental data as a primary research objective: for example, half of the report[8] on excavations at Farmoor, near Oxford, is concerned with the analysis and interpretation of environmental material. New techniques, such as froth flotation, have been developed to allow recovery of more complete and representative samples of biological material; the wealth of material has necessitated new analytical methods[9]

The potential of environmental archaeology in enhancing the understanding of past societies is immense. However, that potential in Britain could not have been realized without the encouragement and financial assistance of the Ancient Monuments Laboratory of the Historic Buildings and Monuments Commission for England (formerly of the Department of the Environment), as part of its 'rescue' archaeology programme. An indication of the importance of that support is provided

by a recent government report[10] which contains a "retrospective/prospective review" of the environmental archaeology of three regions (East Anglia, south-west England and northern England) and one historic town (York) that has been revealed by work sponsored by the laboratory over the past decade. These are the first regional overviews of past environments (as opposed to reports on the environments of specific sites) have been prepared. Although the reports stress problems resulting from lack of data, the information that has been assembled has produced several syntheses with profound implications for archaeology For example, precise information on forest clearance and farming systems is emerging which, together with the results of aerial and ground surveys, radically changes the accepted view of the extent and nature of prehistoric and Roman settlements Analysis of animal bone assemblages is throwing new light on dietary habits, animal husbandry and butchery practices. Analysis of large assemblages of human skeletal material, especially from urban cemeteries, is producing much invaluable — and often unexpected — palaeodemographic and palaeopathological data, which can be related directly to conventional archaeological data

Whereas the enormous potential of environmental archaeology is clear, the government report also emphasizes the inadequacy of funds to more than nibble at the edges of the subject, the material for which is becoming more voluminous with every excavation. Nevertheless, the report is a well-documented exposition of the value of treating human communities as components of a complex ecosystem rather than as isolated phenomena that do not interact with their environments This is where the future lies for archaeology: let us hope that this will be realized by those who can make that future a reality. □

Aggregation

Models of the sol – gel transition

from George Hentschel

ANYBODY who has seen a cold soup turn into jelly has witnessed a sol–gel transition. This is caused by the branching reactions that occur in the polymerization of polyfunctional monomers in a solvent. The gel point separates a sol phase, consisting of a distribution of growing but finite clusters in the liquid medium, from a gel phase where a macroscopically large branched network spans the system with fluid in its interstices. Yet, even today, it is not known whether monomer diffusion allows some reaction sites on the surface of a growing cluster, or whether one can treat all possible growth sites on an equal basis. A new kinetic-growth model, introduced by P. Meakin and Y. Termonia (*Phys Rev. Lett.* **54**, 1083; 1985), now tackles possible diffusion-limited selection by combining aspects of both diffusion-limited aggregation (DLA) and the phenomenon of percolation. This is also critical because the dynamics of a fluid moving through a porous medium will cease to be determined by hydrodynamics when porosity is sufficiently ramified.

The model is a modification of the kinetic growth model of Z. Alexandrowicz for percolation clusters (*Phys. Lett* **80A**, 284; 1980). Place a monomer at the centre S_0 of a hypercubic lattice with coordination number f. Choose a probability P which represents the average fraction of new monomers joining the cluster per unit time At time $t=1$, random variables z_i equally distributed in the interval [0,1] are chosen for each nearest-neighbour site of S_0. If $z_i<P$, a new monomer is placed at the site, whereas if $z_i>P$, the site is blocked for all times. This creates a set of new monomers S_1. In the original model of Alexandrowicz, for all times $t\geq 2$ the algorithm described above is repeated for each new set of branch tips created at the previous step and not blocked. This identifies the sets $S_2, S_3, \ldots, S_t$ of new monomers which join the growing cluster at each unit interval until for $P<P_c$ a point is reached where no new branch tips are created, as all possible growth sites are blocked. For $P>P_c$, the growth does not stop and a macroscopic cluster will span the lattice.

The novelty in the model of Meakin and Termonia is their contention that growth sites are not all created equal As in DLA, the probability P_i for a branch tip on the surface to react with a monomer is larger than for one embedded in the cluster: monomers have to diffuse into the bulk to reach such a growth site and are likely to have reacted before they can do so. To estimate the P_i for each new branch tip in this model, a large number of random walks from each vacant site is simulated and the fraction that escapes from the aggregate gives the relative probability of a monomer reaching that site. To find the absolute probabilities P_i, these relative probabilities have to be normalized so that an average fraction P is likely to be incorporated into the cluster at each step of the growth Once the P_i have been estimated, each possible growth site is occupied or blocked by a new monomer according to whether a random number z_i chosen from the equal distribution [0,1] is less than or greater than P_i. As in the case of percolation, a gel-like transition takes place at some critical rate of incorporation of monomers, P_c. The clusters are fractals with a fractal dimension which is that neither of DLA nor of percolation but, rather, more tenuous.

To see this model in the context of previous attempts to understand the gel point, note that diffusion has usually been neglected completely, and the rate-determining step assumed to be the reaction. All unreacted groups on a polyfunctional monomer were treated as equally likely to react, so there were no geometric constraints in the model. A Smoluchowski equation could be set up with reaction rates proportional to the product of unreacted species in each cluster, and solved for the cluster distribution. This model is soluble and exhibits a sol–gel transition. Though the model is satisfactory away from the gel point, the classical exponents do not agree with experimental results close to P_c.

One geometric constraint that can be introduced easily into the reaction process is to argue that some unreacted sites in the cluster may not be able to react because they are blocked, with some probability P by their neighbours This would allow one to compare percolation and gelation to see whether they lie in the same universality class, as they both show transitions from finite to macroscopic spanning clusters. Unfortunately, percolation exponents are also in disagreement with experimental findings.

In the new model, the ease or difficulty of finding a partner in a unreacted group depends on the ability of a monomer to reach it, as well as blockage by its neighbours. The critical exponents of this model lie between those of classical theory and percolation. Meakin and Termonia compare their model with experimental tests and conclude that it agrees better than do either the percolation or the classical models, although discrepancies still exist. Clearly, monomer diffusion is important in clustering close to the sol–gel transition □

Extracted leaf protein in British agriculture

SIR — Extracted leaf protein (LP) is not made commercially in Britain and there is little research on it here. It is made commercially in Denmark, France, Italy, Japan, New Zealand, Poland, Spain, the United States and the Soviet Union. Because it is possible that it is we who are out of step, it seems timely to reconsider the arguments for LP production.

No one has questioned the argument, advanced more than 40 years ago and amply confirmed experimentally since, that the annual yield of protein in the form of LP can be greater than the yield of a protein concentrate by any other type of farming. Similarly, the demonstrations that LP can replace fishmeal or soy in pig and poultry diets, made 20 years ago in the National Institute for Research in Dairying and the Rowett Research Institute, have been confirmed in many other institutes. The residue remaining after protein extraction contains less water than any crop normally dried for conservation as winter feed for ruminants. Logically therefore, drying should be economical. There is ample evidence that the residue, because non-nitrogenous material is extracted as well as protein, still contains 1.5 to 2.0%N (in the dry matter) and that it makes good silage from which there is no wasteful and polluting effluent. This residue, whether fresh, dried, or ensiled is readily eaten by ruminants. Many experiments show that its feeding value is, weight for weight, as great as that of the original crop: this is presumably because more of the N in it is true protein and because comminution makes it more readily digestible.

One reason for the relative lack of interest in Britain in the use of LP as an animal feed, is the emphasis that has been put here on its value as a human food in countries with a humid climate and protein deficiency. As a result of successful human feeding trials, there are in these countries several production units managed by local enterprise rather than by sponsorship from outside. Its value and acceptability are now established. Even vegetarians in Britain usually eat diets containing an adequate amount of protein. There is therefore little need here for this application of LP. However, we feed pigs and poultry on imported fish meal, ground nut meal and soya: these could be largely replaced by home-produced LP. That substitution would not exacerbate the widely condemned overproduction of agricultural products. On the contrary, while economizing on imports, it would offer farmers an alternative to those crops which are now over-produced.

Another reason for lack of interest is that insufficient attention has been paid to the number of potential sources of LP In early work at Rothamsted, a dozen suitable sources were described: the list could be extended, and it has been further extended in tropical countries. But in most countries where there is commercial production, attention is confined to grass mixtures and lucerne. The latter is agronomically attractive, but its juice froths inconveniently and, unlike some other species, it yields LP with an unappealing flavour. LP can also be extracted from by-products such as potato haulm, sugar beet tops and vegetable discards If effort were put into collection, by-products could supply 100,000 tons of protein anually in Britain as well as a residue suitable for cattle feed.

Yet another reason for lack of interest is the use of unsuitable equipment and techniques in such large-scale trials as have been made. High-speed pulping equipment was used in early work at Rothamsted because we were sure it would work: it is still the most satisfactory equipment in agronomic studies. But pulping by slow-speed rubbing, or extrusion through a die, uses less power and is nearly as effective. If the pulp is less than 1 cm thick after pressing, and if pressure is maintained for a few seconds, juice expression is satisfactory with 1 to 2 kg force per cm^2 (100 to 200 kPa). The vast screw expellers, which have been used in some unsuccessful trials, are extravagant and perform poorly because tightly packed fibre impedes the outflow of protein-rich juice. There are simpler and cheaper methods for expressing juice: more should be devised, for this is the least satisfactory part of the process.

Lack of success in feeding trials with unfractionated juice was predictable. Its protein content is small and variable, its cation content is often excessive and, with some species of leaf, it contains unappealing or slightly toxic components When a production routine has been established, there is no need to separate coagulated LP completely from the juice. If the coagulum is allowed to settle, the sediment has a relatively constant composition, and the supernatant carries away most of the deleterious material. Furthermore, if conservation is necessary because of an uneven supply of leaf, the compact sediment needs less of the preservative. Heating is preferable to any other method of coagulation. It is an illusion to regard it as expensive. Much of the necessary heat can, with a counter-current arrangement, be supplied by juice which has already been heated. If the pulper is driven by a diesel or steam engine on site, exhaust heat will be more than adequate for coagulation.

Without an estimate of costs, the place of LP in British agriculture cannot be assessed. Costs are obviously inflated when the equipment used is more elaborate and expensive than necessary, and when the value of the residual fibre as cattle feed, and the possible value of the fluid which is separated from the coagulum, are not included in the calculation. So many factors tend to invalidate the gloomy conclusions drawn from trials which made inadequate use of existing knowledge and experience, that it was premature to decide that LP production would not be advantageous in Britain. No one has rebutted the basic propositions on which advocacy of LP production depends. The objective is sound, but execution has hitherto been faulty.

Calmodulin and eukaryote evolution

SIR—Whilst reading the recent report by Sudhaker Babu *et al.*[1] on the three-dimensional structure of calmodulin, I was again impressed by this protein's ubiquitous role in eukaryotes. From cotton seed to rat testis it shows itself in a remarkably constant condition and appears to show that a similar ancestor must have been present at the dawn of eukaryote evolution.

Rightly or wrongly the next step is to review the prokaryotes for 'ancestral types' and *Escherichia coli*[2] has a contender in the form of the acyl/carrier protein which has a section resembling that of the E-F hand[3] structure. Also, the antibiotic amphyomycin has been shown[4] to have a calcium dependent action upon Gram-positive bacteria. Its structure[5] shows it not to contain an E-F hand (it only contains 11 residues) but at least a second finger, that is, the loop of the helix–loop–helix described by Kretsinger and Barry[3].

If the evolutionary link between *Streptomyces* antibiotic production and eukaryote calmodulin seems far-fetched, does this mean that the second finger of the E-F hand is the only decent way to employ amino acids in the capture of calcium ions?

Scientific Correspondence is intended to provide a forum in which readers may raise points of a rather technical character which are not provoked by articles or letters previously published (where Matters Arising remains appropriate).

A new approach to an absolute timescale from measurements of orbital cycles and sedimentary microrhythms

Michael R. House

Department of Geology, University of Hull, Hull HU6 7RX, UK

When the sedimentary microrhythms of two groups of Jurassic zones forming part of the chronostratigraphical scale are analysed against recent radiometric age scales there is good agreement with present-day cycles resulting from the obliquity of the ecliptic. Sedimentary microrhythms resulting from orbital forcing can be used to establish either the relative or the true length of chronostratigraphical zones and thus provide a new approach towards an absolute timescale. Such a scale will be powerful in the analysis of other cycles and perturbations in the geological record.

THE inadequacies of the radiometric timescale for practical use in much of the Phanerozoic sedimentary record is well known. Reliance has always been placed on the relative timescale provided by evolutionary changes for local and international correlation and age determination. It is the biostratigraphical and chronostratigraphical scales[1] which form the standard for geological work on sedimentary rocks on land an in the oceans. But a numerical scale is obviously required for any useful analysis of sedimentary, tectonic and evolutionary processes. I show here how recognition of a causation for some sedimentary microrhythms in terms of the influence of orbital forcing cycles can provide a new approach to the establishment of an absolute timescale, using the evidence of the effect of such cycles in comparatively recent deep-sea cores[2-4] and the recognition that sedimentary microrhythms common in the stratigraphical record[5,6] may result from Milankovitch-type cycles[7].

I will use two examples from the Jurassic to illustrate the technique. These examples enable integration with the chronostratigraphical scale. The Jurassic also demonstrates the essential problems with the current radiometric timescale. Table 1 lists several recent attempts to give the duration of the Jurassic and shows the uncertainty of each method. As to the finer divisions of the Jurassic used on radiometric scales, three approaches have been used recently. The first is to consider the 10 or 11 Jurassic chronostratigraphical stages to be of equal duration and to divide the number into the accepted duration for the system[8]. The second is to take the number of ammonite zones within a stage as the more reasonable estimate of its duration and to adjust stage length accordingly[10]. The third proposal[11,12] is a weighted scheme using zonal and subzonal divisions. All three methods are based on the assumption that the evolutionary changes, which form the basis for stage, zonal and subzonal division, proceed at a uniform rate. Yet that is an hypothesis which a palaeontologist would wish to test, and the evidence presented here shows that is false.

Sedimentary microrhythms

There has been a wide recognition of rhythmic sedimentary events[5,6,13] at a scale of ~0.2–3.0 m throughout the Phanerozoic and parts of the Precambrian. However, these rhythms are usually asymmetrical cycles of the ABCABC or ABCDABCD type, and there seemed little immediate relation to the regular symmetrical cycles (such as ABCDCBA) which one would expect from orbitally controlled patterns. Perhaps that is a reason why such interpretations have been regarded as speculations. Figure 1 illustrates how rhythmical or asymmetrical cycles may rise from symmetrical forcing oscillations when set against a regular trend in a changing parameter, for example, sea-level

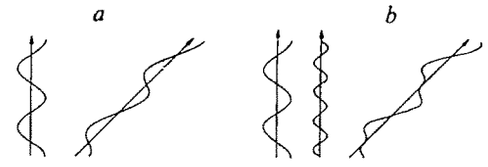

Fig. 1 Net effect of symmetrical oscillations and long-term trend giving a stepped effect of stasis and more sudden change. This model can be interpreted, for example, in temperature, sea-level, salinity, faunal abundance or climatic terms. *a*, Effect of one cycle; *b*, effect of two cycles, such as the tilt and precession cycles.

change against a subsiding sea floor, temperature oscillations against a progressive temperature change or climatic oscillations against a climatic trend. The simple patterns illustrated in Fig. 1 show a period of rapid change followed by relative stasis of the type needed to explain many microrhythms. Such a situation may be provided by a combination of the Milankovitch-type orbital oscillations[7]. More complex interpenetration of several cycles and combinations of cycles with different control could give very elaborate effects. In such cases, different amplitudes and wavelengths can give harmonics and varieties of pattern which might, at first glance, seem bewildering, but which would have simple primary cause[9]. This is illustrated in Figs 1 and 5 which show how the effects of simple cycles which can be resolved using Fourier transforms.

Many microrhythms in the geological record result from quite different causes, for example, turbidite flows resulting from continental shelf and slope instability, nearshore storm events, periodic fault movements or spasmodic volcanicity. Orbitally related phenomena may be best studied in deeper sedimentary basins away from such phenomena. To proceed with the construction of the new timescale only a few sequences well-related to the chronostratigraphical scale are needed, then normal biostratigraphical techniques can be used.

Jurassic examples

To demonstrate a possible relation between sedimentary microrhythms and orbital patterns two cases will be considered from English Jurassic sequences which form part of the chronostratigraphical scale, one from the Lower and one from the Upper Jurassic. Figure 2 illustrates the typical sequence for the south of England along the Dorset coast. The large-scale rhythmicity shown is not of concern here but was appreciated as early as 1822 (ref. 14) and has been described in detail elsewhere[15-17]. Each of these major rhythms usually show finer-scale microrhythms, the immediate cause of which have been investigated extensively in terms of small sea-level changes and anoxic events[16]. Two examples will be treated here, part of the Lower Lias and part of the Kimmeridge Clay, chosen because their unambiguous relation to the chronostratigraphical scale. The initial postulate for this study is that the observed regular small-scale rhythmicity indicates the overprinting of a periodic enrivonmental change.

The careful measurements of the Lower Lias microrhythms of Lyme Regis, Dorset by Lang form the basis for the calculations given here[18,19]. The microrhythms typically comprise a thin laminated, dark, organic-rich shale followed by lighter coloured calcareous shale with bioturbated limestone beds at the top[20-22]. Not all units are developed and higher in the succession the limestone units are often lost. The succession of these microrhythms and their correlation with the standard chronostratographical scale[23] is illustrated on Fig. 3*a* using Lang's data and terminology for bed numbers. The Lower Lias sequence is nearshore and could be expected to be incomplete[23]; it represents a deepening sequence from possible supratidal stromatolitic Upper Triassic beds below. Some data from Somerset[24] are also considered.

The broad features of the Upper Jurassic Kimmeridge Clay have been described[25-27]. The typical microrhythms comprise alternations of well-laminated oil shale and/or laminated organic-rich shale with more calcareous, lighter coloured shale or mudrock. This sequence is interrupted by dolomitic or coccolith limestone bands, termed stone bands, which form convenient markers. Immediately above these markers microrhythms are often not clearly seen. The Blackstone, or Kimmeridge Oil Shale, is the best developed and thickest oil shale. This and associated oil shales are thought to be the main source of oil in the North Sea fields and for the nearby Wytch Farm field (Fig. 3*b*)[26]. An illustration of a cliff section showing some of these microrhythms is given on Fig. 4*b*.

Analysis of microrhythm data

Only Arkell[28] in this century has had sufficient detailed biostratigraphical command of the whole Jurassic to give judgement on zones which might have reasonable balance throughout the system. He used 58 zones, excluding the non-marine Lulworth Beds to which we may assign two zones for calculation, giving 60 in all. Arkell's subdivision of the Kimmeridge Clay was provisional and if revisions of the sequence between the Mutabilis and Pectinatis Zones[25,26] are accepted, the total of zones is not altered but all the Kimmeridge Clay data on Fig. 3*b* can be used. More recent lists give up to 74 zones[23]; if this value is preferred other calculations may be done, but I feel that this introduces too much relative subdivision at certain levels.

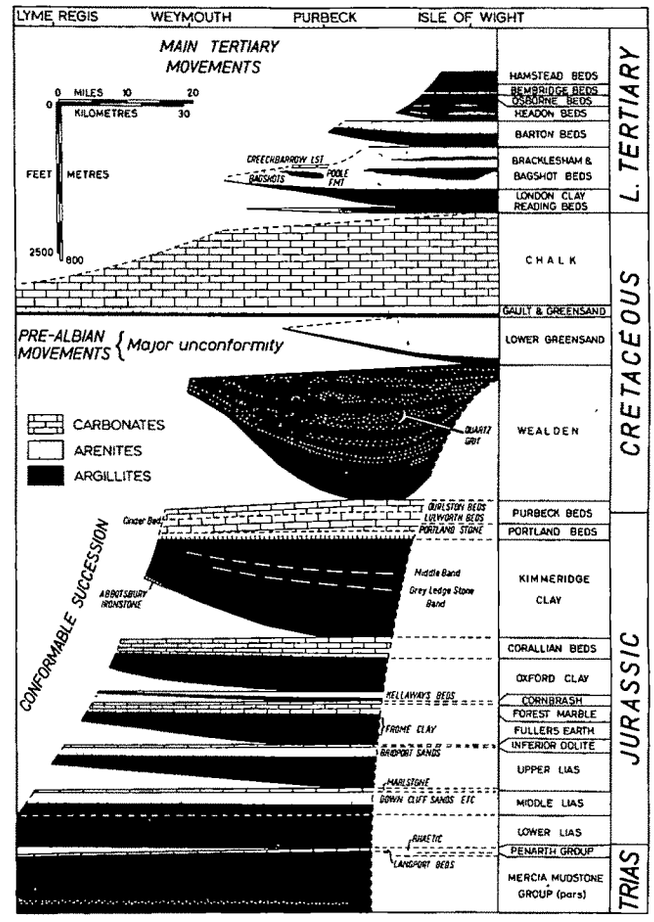

Fig. 2 Mesozoic and Tertiary sequence of the Dorset coast drawn to emphasize the large-scale rhythmicity of the succession and to indicate the levels of the sequences discussed in greater detail (after ref. 14).

The four earliest Jurassic zones used here[23] compare with the first three of Arkell's scheme[28] to estimate zone duration. Using Lang's limestone units for the first approximation (Fig. 3*a*) these give the following crude numbers of microrhythms for each zone. (Shown in parentheses are interpolated rhythms which have been added for use in the calculations.) Planorbis Zone (beds H25–H56), 16(6); Liasicus Zone (beds H57–H83), 13(6, assuming six rhythms when complete between each of refs 2–4), Angulata Zone (beds H84–20), 19(5); Bucklandi Zone (beds 21–46), 13 (14). This gives a total of 91 for the four zones (three in Arkell's scheme[28]). No estimate is made for the Semicostatum Zone, but rhythmicity clearly continues (Fig. 3*a*).

Data from Somerset[24] suggest that at Doniford Bay the following values hold: Planorbis Zone (beds 14–42), 10; Liasicus Zone (beds 43–69), at least 18; Angulata Zone (beds 80–145), 39 (or 40 at Blue Ben); Bucklandi Zone (beds 146–203), 27. This gives a total of 94 microrhythms. But there is considerable subjectivity in the estimation of these numbers and some discrepancy between them and those of Dorset. The Lias evidence is used in the absence of better data, but a more thorough regional and international study should provide more reliable values.

The Kimmeridge Clay microrhythms used for the calulations are shown in Fig. 3*b* where interpolated levels are the numbers

Table 2 Estimates of the time duration of microrhythms of the Lower Lias (Planorbis to Bucklandi Zones) and Kimmeridge Clay (Autissioderensis to Wheatleyensis Zones)

Duration of Jurassic (Myr)	Duration of each zone (Myr)	Duration of Lias rhythms (kyr)	Duration of Kimmeridge rhythms (kyr)	Average (kyr)
60	1.00	33.0	40.8	36 9
65	1.08	35.6	44.1	39.8
70	1.17	38.6	47.8	43 2
75	1.25	41 2	54 9	48.1

Several possible duration times are used for the Jurassic, and it is assumed that the zones are typical in length for the Jurassic using a slight modification of Arkell's zonal scheme[28] (see text for details and the effect of other assumptions).

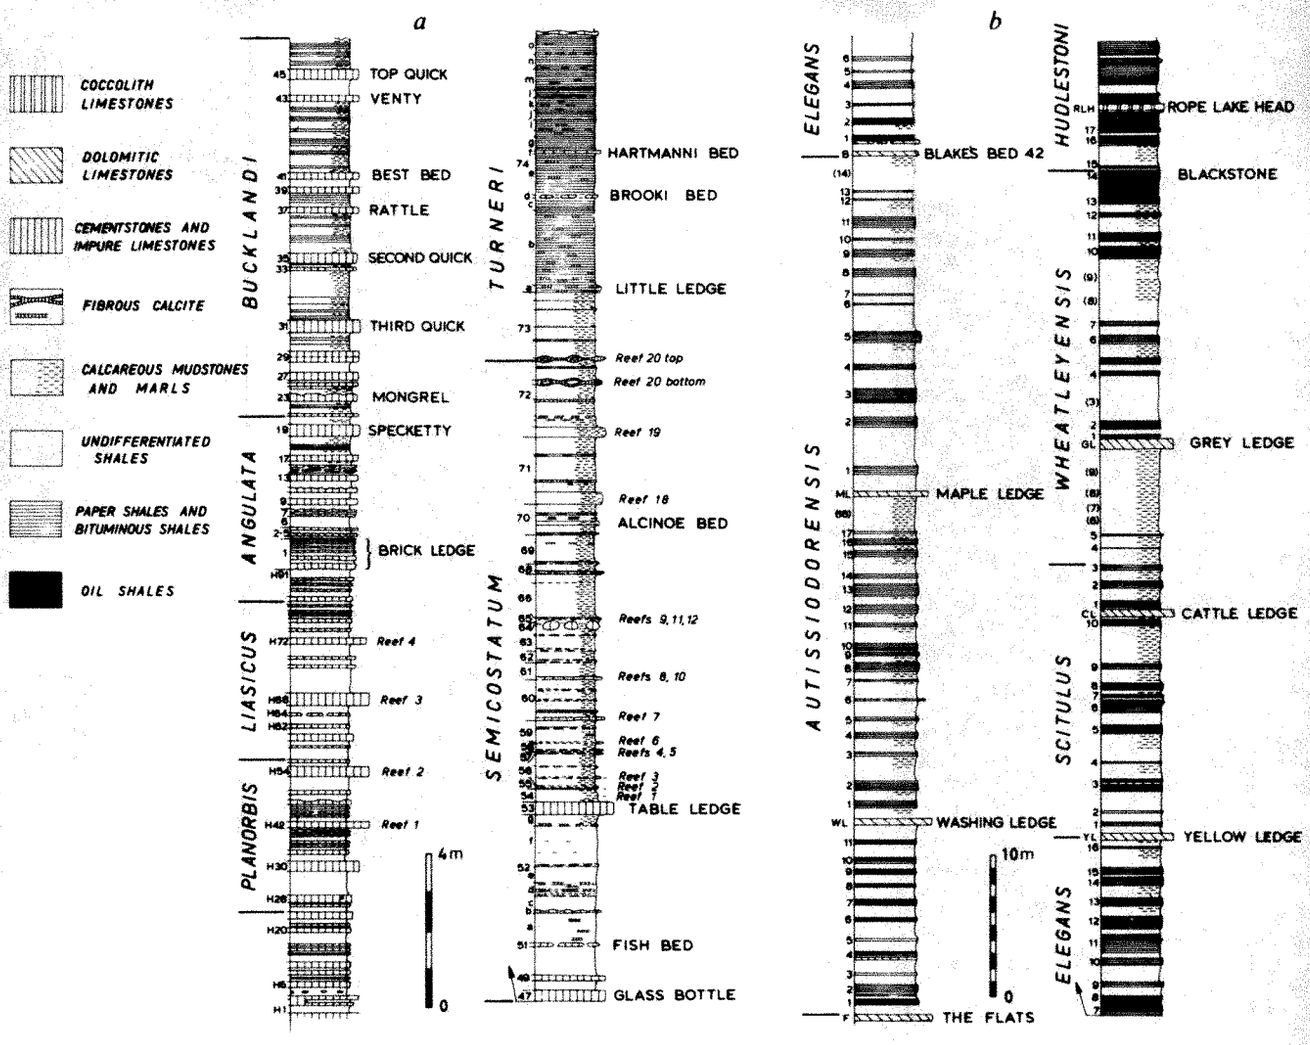

Fig. 3 Detailed sequences from the Jurassic of the Dorset coast illustrating sedimentary microrhythms. *a*, Part of the Lower Lias of the coast near Lyme Regis based on detailed descriptions and bed numbers of Lang[18,19]. The base of the Jurassic and Hettangian Stage is taken where *Psiloceras* enters in bed H25 and the base of the Sinemurian is taken at Bed 21. Numbers with prefix H refer to the section west of Seveh Rock Point, those without prefix extend from the Point eastward to the foreshore below Black Ven. *b*, The section near Kimmeridge between Kimmeridge Bay and Clavell's Hard based on published data of Cox and Gallois[25]. The bed numbering is new and the marker beds are abbreviated so that they form a prefix for the bed numbers given above them up to the next marker bed. A numbering system is given for reference which refers to units above particular marker beds. Thus, ML5 refers to fifth organic-rich shale above the Maple Ledge Stone Band. The boundary between the Lower and Upper Kimmeridgian (*sensu anglico*), and between the Kimmeridgian (*sensu gallico*) and Tithonian stages is usually drawn at Blake's Bed 42 (B).

in parentheses. Zonal assignments are those of a recent revision[26]. The numbers used are as follows: Autissiodorensis Zone (F1 to MP14), 45; Elegans Zone (B to B16), 17; Scitulus Zone (YL to CL3), 15; Wheatleyensis Zone (CL4 to GL14), 21. This gives a total of 98 microrhythms. Table 2 gives calculations of the time for each microrhythm using only the Dorset data.

Interpretation

There are several uncertainties in the values used, of the period taken for the length of the Jurassic, of the number of Jurassic zones and of the assumption that the eight zones used are a fair sample for the Jurassic. Nevertheless, the agreement of an average of the microrhythm period and an average of current estimates of the duration of the Jurassic with the value of 41 kyr (ref. 4) which is the oscillation resulting from the obliquity of the ecliptic at present is very close (Table 2), perhaps fortuitously so. The differences between the Lias and Kimmeridge results could be due to different weighting in the true zonal periods involved. I suggest that the obliquity cycle may be the primary cause of the dominant rhythmicity. If the obliquity periodicity has changed little through time, then estimates of the duration of the zones, using the 41-kyr value give the following results (in Myr): Planorbis Zone, 0.86; Liasicus Zone, 0.78; Angulata Zone, 0.94; Bucklandi Zone, 1.11; Autissiodorensis Zone, 1.84; Elegans Zone, 0.7; Scitulus Zone, 0.62; Wheatleyensis Zone, 0.86. For the present, these values should only be taken, in their blocks of four, as relative times which may be assigned to the zones. Note that if the 41-kyr cycle did hold in the Jurassic these values indicate (within the limit of sampling) which duration is the more probable for the Jurassic. The present evidence would favour the Cambridge scale[36], but other time and zonal scales give different results because of unbalanced zonal weighting. Thus, Hallam[29] gives the Kimmeridgian (*sensu gallico*) and Tithonian 22 zones and a span of 11 Myr, which would give a period of 20.4 kyr for the Kimmeridge microrhythms. Data from the same review would give an average of 62.5 kyr for the Hettangian microrhythms (giving, as expected, an average of ~41 kyr). The true value will only be approached when relative lengths for zones, using the technique proposed here, are assembled throughout the Jurassic. But do such errors explain the diversity of estimates of microrhythm duration in other parts of the stratigraphical column[7]?

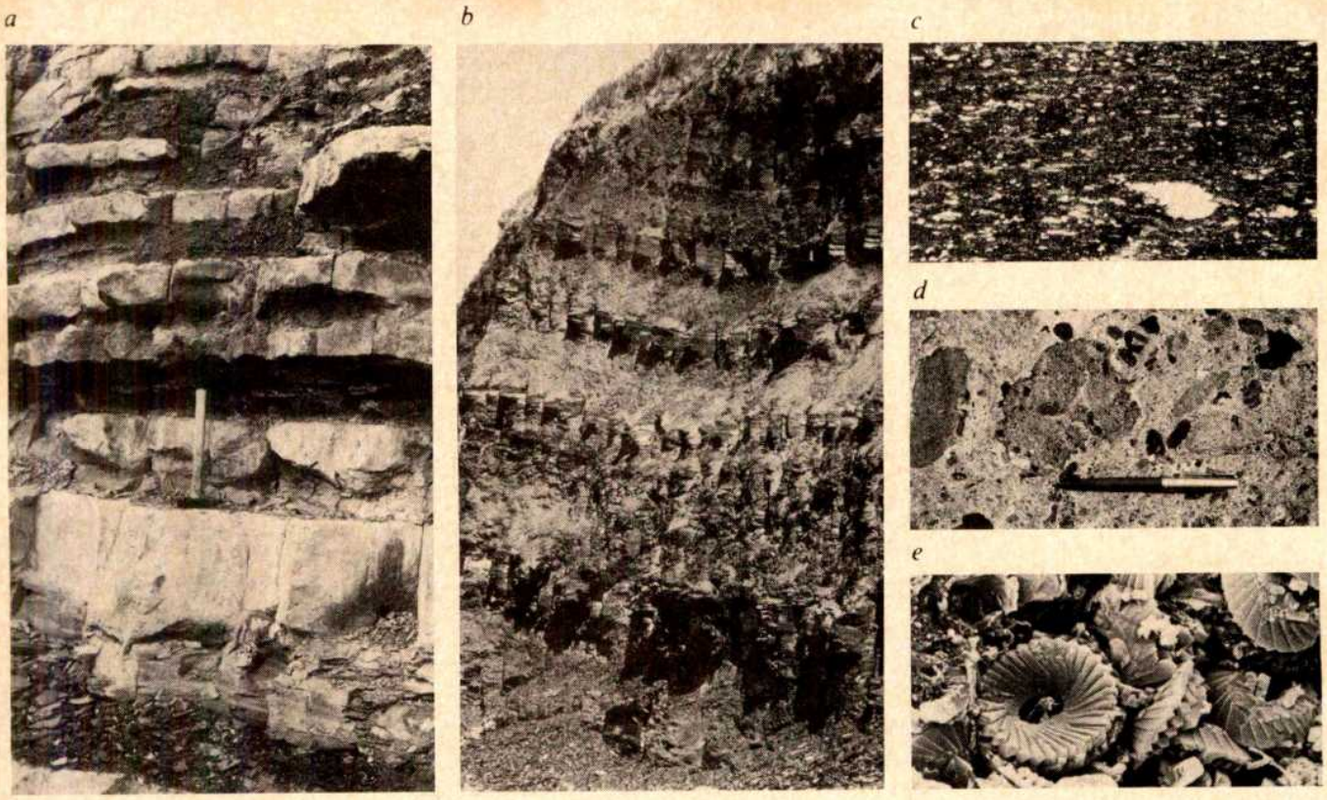

Fig. 4 Features of Dorset Jurassic sedimentary microrhythms. *a*, Part of the Lower Lias succession in Chippel Bay, west of Lyme Regis. The hammer is on the unit called Specketty (Bed 19). *b*, A cliff profile in Kimmeridge Bay, just west of Gaulter Gap, showing the weathering profile of microrhythms above The Washing Ledge Stone Band (Bed WL2 is at the base of the cliff). Four zones are represented (Autissiodorensis to Wheatleyensis). *c*, Section of The Blackstone (Bed GL14) illustrating clasts within the spore-rich oil shale. *d*, Debris deposits in the White Stone Band west of Freshwater Steps, Kimmeridge. Pen, 13 cm long. *e*, Stereoscan photograph of a specimen from the Rope Lake Head Stone Band showing well-preserved coccoliths without a trace of biodegradation. Width of photograph, 15 μm.

The obliquity cycle operates by the shifting of latitude and the microrhythms may be explained, for example, by small climatic shift[29,30]. Thus, oscillations in and out of the tropical forest belt might explain the organic-rich, anoxic phase and the hitherto anomalous evidence for turbid flow and coarse debris within parts of oil shales and organic-rich shales in the Dorset Jurassic (Fig. 4*c*, *d*). This provides a better model than reliance on sea-level changes, although these may be involved in some cases. Perhaps the most promising model is that invoking cold-water benthic versus warm-water planktonic regimes[31]. Although the amount of variation in tilt is likely to be less in the past because of the greater number of days in the year, it seems reasonable to suppose, as a working hypothesis, that the period of the obliquity cycle is probably constant.

Clearly, there are other oscillations that may affect the system, both at greater and smaller frequencies. Thus, the Lias Beds H30 to H66 show three major units forming the reefs, each separated by five minor limestones, which may indicate six oscillations between the maxima of a larger cycle. The Lias sequence discussed here has been the subject of Walsh power-spectra analysis, suggesting orbital-precession (19 and 23 kyr) and a 31-kyr obliquity cycle in addition to those mentioned[30]. These values depend on the assumption of 1-Myr zones and of sedimentation rates. The effect of such cycles seems limited to the introduction of irregularities in the rhythmic pattern. In the group of zones considered here, limestones comprise ~25% and argillites the remainder. A single, probably varved, limestone from above the Brick Ledge gives a 'varve' average of 850 μm. Estimates for varves in organic-rich levels have been given[20] as 9–17 μm and the average, 14 μm, may be used for calculation. Given a total thickness of 25.6 m, these values suggest a depositional time of 1.5 Myr when the expected duration for average zones would be ~4 Myr giving a total of time hiatus of 62.5% comparable with another recent estimate[30] of 70%. But I suggest here that the major rhythmicity signature, estimated as 41 kyr, is probably nearly complete and the loss occurs in individual rhythms.

The Kimmeridge data suggest a repetition of coccolith limestones or dolomitic limestones with a cycle, perhaps a harmonic of about twice or three times that shown in Lias Beds H30 to H66 referred to above. Such signatures of oscillation interaction may prove to be time definitive. A computer model, from a program by R. Middleton, is shown in Fig. 5, and will be used to illustrate an interpretation of the Kimmeridge Clay data. The dominant periodicity (41 kyr) is that obtained by present calculations. The expected 100-kyr cycle is added weakly as it shows no very obvious visual effect. The largest period (taken at 451 kyr) is suggested by the stone band position (F to F11, YL to YL10, CL to CL(9) taken as about 11 times the supposed obliquity cycle) and is used to illustrate the fact that the different controlling oscillations may operate differently. Thus, the points marked *a* on Fig. 5 show times when climatic shift crosses the environmental threshold, enabling the production of organic-rich or oil shales, the threshold being indicated by the straight line given an arbitrary trend. This threshold will be expected to vary from place to place and, in particular, anoxia will reduce in shallower and more agitated waters. At the points marked *b* in Fig. 5, however, the threshold is not crossed and the rhythms may not be obvious in the sediments and they will not show as organic-rich shales. This is the justification for the interpolations used in the calculations (Fig. 3*a*, *b*). A cycle of larger wavelength affecting the shape of the orbit, similar to the present-day 100-kyr cycle (but given on the model a 451-kyr periodicity), could result in periods of much higher global insolation and hence, for example, in more extreme temperatures. This might explain periods of coccolith blooms (Fig. 4*e*) and the periodic formation

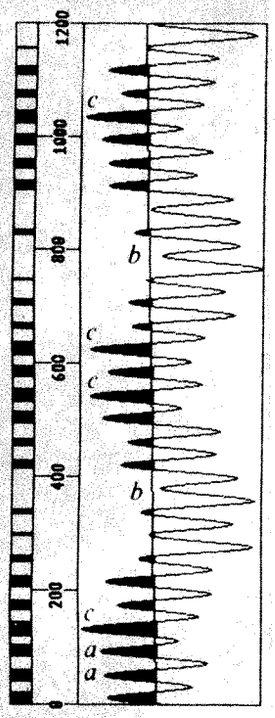

Fig. 5 Computer simulation of microrhythm patterns using 41 kyr as the main obliquity periodicity with amplitude taken as unity. Additional oscillations arbitrarily introduced at wavelengths of 451 and 100 kyr with amplitudes of 0.6 and 0.3, respectively. The vertical column indicates conditions when organic-rich shales may be produced if the trend line represents an environmental threshold for their formation. Scale in kyr.

of the marker stone bands, which would be under quite a different control from the obliquity latitudinal shift. Two such cycles could interpenetrate in their magnitude and in their effect. In this interpretation, it is assumed that the carbonate marls necessary for the production of the diagenetic dolomitic stone bands[32] arise from pelagic carbonates formed on occasions similar to those producing coccolith blooms. A small portion of this sequence, including the Blackstone, has been the basis of Fourier analysis using detailed chemical data[33] and assumptions of sedimentation rate has given evidence of smaller-scale cycles. When the chronostratigraphical scale for the Jurassic is calibrated numerically by the summation of relative duration data, Walsh power spectral analysis and Fourier analysis should enable the provision of very precise astronomical data on planetary perturbations.

At a larger scale are the rhythms producing widespread anoxia in the Jurassic in the Toarcian, Callovian and mid-Kimmeridgian (*sensu anglico*) but whether they have a regular period has still to be demonstrated.

The many examples of rhythmicity described in other parts of the Jurassic and in other stratigraphical systems need to be studied to contribute to the calibration of the timescale and the establishment of a numerical scale linked to the chronostratigraphical scale along the lines suggested here for the Jurassic. It should be emphasized, as is illustrated by Table 2, that even in the relatively well-known Jurassic, bizarre results may follow the choice of an inaccurate radiometric time scale. Subject to the monitoring suggested here, orbital forcing patterns may become the more reliable tool.

Conclusions

If the microrhythms discussed are periodic then, whatever their cause, they provide a better means of assessing the relative lengths of zones for purposes of subdividing the radiometric timescale than the present assumption that stages, zones or subzones are of equal duration.

Assuming values for the average duration of blocks of Jurassic zones based on current radiometric scales, the period for the microrhythms discussed accords well with the present value (41 kyr) for the period resulting from the obliquity of the ecliptic. If this is the primary cause of the sedimentary rhythmicity then it can be used to estimate the absolute length of zones. But other values result from different premises.

It is argued that either relative methods or, eventually, orbital cycle methods can be used to build up a precise date in years for zonal sequences so that the chronostratigraphical scale can become a numerical means of estimating geological processes quantitatively.

I suggest that such a quantitative scale is the only convincing way in which larger-scale stratigraphical and palaeontological perturbations can be dated and interpreted.

I conclude that the assumption made in subdividing the existing radiometric timescale that zones or subzones are of equal duration is false.

If the primary cause of the main rhythms examined is periodicity in the angle of the Earth's tilt then the interpretation of them in terms of slight shifts of climatic belts becomes reasonable. Other rhythms may have quite different orbital forcing controls, such as global insolation changes. The examples given are intended to illustrate a technique rather than to provide final values or interpretations for the phenomena discussed.

Amino-acid substitutions at codon 13 of the N-*ras* oncogene in human acute myeloid leukaemia

DNAs from four out of five patients with acute myeloid leukaemia (AML) tested by an in vivo *selection assay in nude mice using transfected mouse NIH 3T3 cells were found to contain an activated N-*ras *oncogene. Using a set of synthetic oligonucleotide probes, we have detected a mutation at codon 13 in all four genes. The same codon is mutated in an additional AML DNA that is positive in the focus-formation assay on 3T3 cells. DNA from the peripheral blood of one patient in remission does not contain a codon 13 mutation.*

THE use of focus assays to detect morphological transformation of NIH 3T3 cells in DNA transfection experiments has shown that between 10 and 30% of human tumours contain altered forms of either the c-Ha-*ras*-1 gene, the c-Ki-*ras*-2 gene or the N-*ras* gene. These genes encode GTP-binding proteins of 188 and 189 amino acids that are located at the inner surface of the cell membrane and which are evolutionarily highly conserved[1,2]. In the 15 or so cases of altered *ras* genes in human tumours that have been analysed so far, activation has been shown to result in a single base pair mutation which leads to the substitution of either a glycine at amino acid 12 or glutamine at amino acid 61 (refs 3–17). However, *in vitro* mutagenesis experiments have shown that mutations at amino acids 13, 59 and 63 can also lead to transforming activity[18].

We have studied the presence of activated *ras* genes in acute myeloid leukaemia (AML), a disease characterized by abnormal proliferation and differentiation of cells of the myeloid, monocytic and erythroid lineage. This disease is subdivided into six groups (FAB M1–M6; ref. 19) according to which immature cell is dominant in the population. Using a direct *in vivo* selection assay in nude mice of transfected 3T3 cells[20], we find that four out of five AML DNAs tested contain an activated N-*ras* gene. An altered N-*ras* oncogene was also detected in another AML sample using the focus-formation assay. We analysed these activated N-*ras* genes for the presence of mutations using a set of synthetic oligonucleotide probes and report here that all five activated N-*ras* genes are found to contain a mutation at codon 13.

Transfection of NIH 3T3 cells

In initial experiments using focus formation on NIH 3T3 cells as an assay for the transfer of transforming genes, DNAs prepared from five samples of AML cells were found to have low, if any, transforming activities (D.T. and C.J.M., unpublished results). However, in a different laboratory one out of three AML DNA samples was found to have transforming activity[38]. Because focus formation may not detect all transforming genes (for example, some alterations to *ras* genes lead to only a minimal change in morphology of the transformed cells[21]), we sought to increase the sensitivity of the transformation assay. Previously, Blair *et al.*[20] have shown that direct *in vivo* selection of transformed cells can be used as an assay for the transforming genes in transfected cells. As an additional step to ensure that all the injected cells had been transfected with donor DNA, DNA samples were co-transfected with the plasmid pSV2Neo (ref. 22) and the transfected cells selected in antibiotic G418. A similar approach has been described by Fasano *et al.*[23], but we injected a smaller number of cells than these authors. We found that tumours arose 30–55 days after inoculations of NIH 3T3 cells transfected with four out of five preparations of DNA from AML samples (AML 33, 49, 73, 77). Of 15 other human tumour DNA samples tested in the same way, 10 failed to give any tumours, even within 90 days, whereas 5 other samples gave tumours 32–80 days after inoculation of transfected cells (Table 1). Normal DNA prepared from either mouse livers or human lymphocytes gave a very low incidence of tumours—0/3

Table 1 Co-transfection and nude mouse tumorigenicity of AML DNAs

DNA + pSV2Neo	FAB classification of AML	Primary tumour incidence per co-transfection of 20 μg DNA	Latent period (days)	Secondary tumour incidence per co-transfection	Latent period (days)
Normal mouse DNA		3/28	94	NT	
Normal human		0/3			
HT1080		3/3, 1/3	30–70	NT	
AML 33	M1	1/3	50	3/4	39
AML 49	M5	1/3, 2/3, 1/3	37	3/3	27
AML 73	M2	1/3	30	1/4	34
AML 77	M4	1/3	55	NT	
AML 50	M5	0/3	90	NT	
15 Human tumours (non-AML)		10×0/3, 4×1/3, 1×2/3	32–80	NT	

20 μg Cellular DNA and 300 ng pSV2Neo were precipitated with calcium phosphate into each of three 60-mm plates seeded 1 day previously with 2×10^5 NIH 3T3 cells; 22–24 h later, the co-precipitate was washed off and the cells incubated in normal growth medium (Dulbecco's modified Eagle's medium + 10% calf serum) for 20 h. Each dish was then trypsinized and seeded to a 150-mm dish containing selective medium with 1 mg ml^{-1} G418. After 7–10 days of growth in selective medium, each dish contained $1–1.5\times10^3$ G418^R colonies and a total of $3–4\times10^6$ cells. 1.5×10^6 cells were then injected into each of two inguinal subcutaneous sites of *nu/nu* mice. NT, not tested.

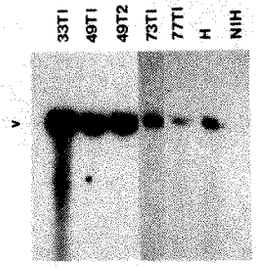

Fig. 1 Southern blot analysis to show the presence of human N-*ras* in NIH 3T3 transfectants from AML DNAs. 33T1, tumour in nude mice derived from co-transfection of NIH 3T3 cells with pSV2Neo and AML 33 DNA; 49T1 and 49T2, two tumours that arose from separate experiments with AML 49 DNA; 73T1 and 77T1, tumours that arose from experiments with AML 73 and 77 DNA, respectively. Control samples are DNAs from normal human fetal lung and NIH 3T3 cells. In each lane 5 μg *Eco*RI-digested DNA was separated. Arrow, 8.8 kb.
Methods. DNAs were digested with *Eco*RI, electrophoresed in a horizontal (0.7%) agarose gel and blotted to nitrocellulose. The filter was hybridized (5×SSC, 20 mM sodium phosphate, 5× Denhardts' solution, 10% dextran sulphate, 50 μg ml^{-1} denatured salmon sperm DNA, 50% formamide) at 42 °C for 16 h with 10^8 c.p.m. ml^{-1} of a ^{32}P-labelled probe obtained by nick-translation of the 800-bp *Eco*RI/*Sst*I fragment of N-*ras* contained in pAT8.8 (ref. 24). This fragment does not hybridize to mouse DNA and detects a single 8.8-kilobase (kb) fragment in *Eco*RI digests of human DNA. After hybridization the filters were washed twice in 0.1×SSC, 0.1% SDS at 60 °C and then exposed to Kodak XAR-5 film at −70 °C with intensifying screens.

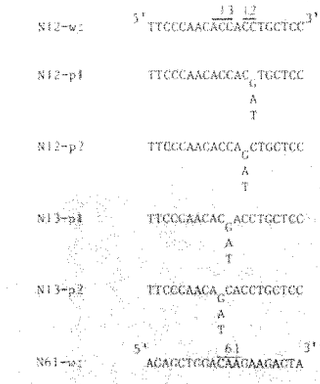

Fig. 2 Sequence of the 20-mer probes used to detect mutations in codon 12, codon 13 and codon 61 of the N-*ras* gene. Sequences are derived from Taparowski *et al.*[12].
Methods. The N12 and N13 probes were synthesized using as template chemically synthesized 20-mer and an 8-mer primer complementary to the 3' end of the 20-mer. This primer-template complex was incubated with [α-^{32}P]dCTP (3,000 Ci mmol^{-1}; Amersham), cold dGTP, dATP and TTP, and DNA polymerase I as described by Bos *et al.*[17]. The 8-mer primer carried a 5'-terminal phosphate group which enabled us to separate the labelled oligomer from the unphosphorylated template on a polyacrylamide urea gel. The N61 probe was synthesized similarly but now using [α-^{32}P]dATP (see ref. 17). The oligonucleotides were prepared by a phosphotriester approach[37] using a fully automatic synthesizer (Biosearch SAM-I).

(human) and 3/28 (mouse)—and any tumours which did appear only arose 90 days after inoculation. DNA prepared from HT1080 cells, known to contain an activated N-*ras* oncogene[24], produced tumours 30–70 days after inoculation in 4/6 co-transfections. The transforming activity detected in the first transfection with AML DNAs could be passaged serially with similar or slightly greater efficiencies (Table 1).

To examine whether any of the tumours that arose in nude mice resulted from the acquisition of a human *ras* oncogene, DNA prepared from the tumours was analysed by Southern blotting with probes for N-*ras*, Ha-*ras* and Ki-*ras*. It was found that DNA prepared from each of the primary transfectants from the four AML DNAs detected by *in vivo* selection (Fig. 1) and the one detected by the focus assay contained the human N-*ras* gene. In some, but not all, transfectants the human N-*ras* gene was amplified 20–30-fold. There was no evidence for transfer of any of the other *ras* oncogenes, and tumours that arose after co-transfection of non-AML DNA did not contain human *ras* genes (data not shown).

Mutations at codon 13

To analyse the transfected N-*ras* genes in the NIH 3T3 transfectants derived from AML DNAs, we used synthetic 20-mer oligonucleotide probes. Using these probes we are able to detect single base pair (bp) substitutions in the N-*ras* gene based on the fact that a fully matched hybrid between the oligomers and genomic DNA is more stable than a 1-bp mismatched hybrid[25]. For the positive detection of mutations, we have synthesized groups of oligomers varying at one position in a codon (see Fig. 2). One oligomer of each group will then hybridize to form a fully matched hybrid with each of the possible mutations in a base pair. For example, the oligomer group N12-p2 consists of three oligomers, one of which will form a fully matched hybrid with an N-*ras* gene mutated at the second base of codon 12.

When *Pst*I-digested DNA from four AML transfectants (33T, 49T, 77T and 1T) was hybridized to the probe corresponding to the sequence of the normal N-*ras* gene around codon 61 (N61-wt) and washed under conditions in which only a fully matched hybrid is stable, a strongly hybridizing signal was seen (Fig. 3*A*). In two transfectants (49T and 33T) the signal was very intense, showing that the N-*ras* genes were highly amplified (see also Fig. 1). No hybridization was seen with the oligomer groups corresponding to mutations at codon 61, indicating that none of the N-*ras* genes in the transfectants contained mutations at codon 61 (data not shown). In contrast, the oligomer corresponding to the normal sequence of the N-*ras* gene at codon 12 (N12-wt) failed to form a fully matched hybrid with any of the AML transfectant DNAs (Fig. 3*B*), although it did hybridize to human cellular DNAs containing single-copy representations of the wild-type sequences at position 12 (lanes *a*, *b*). However, when the transfectant DNAs were hybridized with the groups of probes corresponding to mutations at each of the base pairs of codon 12 (N12-p1, N12-p2), fully matched hybrids were not detected (Fig. 3*C*, *D*).

The absence of fully matched hybrids with either normal or mutant probes led us to investigate whether any mutations occurred in the sequence surrounding codon 12. Recently, Fasano *et al.*[18] have shown by *in vitro* mutagenesis that mutations in codon 13 (Gly) can lead to transforming activity of the c-Ha-*ras*-1 gene. Therefore, we analysed the transfectant DNAs by hybridization with probes (N13-p1 and N13-p2) that could recognize mutations at the first or second position of codon 13. The oligomer group N13-p2 hybridizes with each of the AML transfectant DNAs (Fig. 3*F*). Those transfectants with the highest copy number of the N-*ras* gene showed the greatest signal with the N13-p2 probe, but hybridization was also seen in a transfectant (77T1) that only contains one or a few copies of N-*ras* (compare Figs 1 and 3*F*), whereas no hybridization was detected with control DNAs having the wild-type sequence (Fig. 3, lanes *a*, *b*). Thus, we conclude that the N13-p2 probe forms a fully matched hybrid with the AML transfectant DNAs. No hybridization was detected with the N13-p1 probe to the transfectant or control DNAs (Fig. 3*E*). Therefore, our results show that the transfectant DNAs contain N-*ras* genes with a mutation at the second position of codon 13. Recently, we have found that the N-*ras* gene in transfectant DNA of AML 73 also

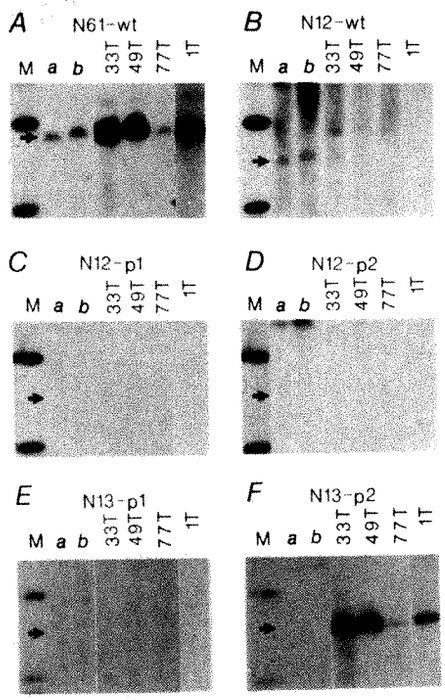

Fig. 3 Hybridization of synthetic oligomer probes to genomic DNA of 3T3 cell transfectants of four different human AMLs. The panels are replicates of each other with DNAs of HL60 (*a*) and HT1080 (*b*) as control and the DNAs of the AML transfectants 33T, 49T, 77T and 1T. The panels were hybridized to different oligomer probes: *A*, N61-wt; *B*, N12-wt; *C*, N12-p1; *D*, N12-p2; *E*, N13-p1; *F*, N13-p2; M, fragments of phage λ DNA digested with *Hin*dIII (4.3 and 2.3 kb). Arrows indicate the position of the N-*ras* fragment.

Methods. Hybridization was essentially as described by Bos *et al.*[17]. Genomic DNA (10 μg) was digested with *Pst*I and electrophoresed on a 0.5% agarose gel. The gels were denatured in 0.4 M NaOH, 0.8 M NaCl, neutralized in 0.5 M Tris-HCl (*p*H 7.2), 1.5 M NaCl and dried. The dried gel membranes were hybridized at 50 °C with N61-wt and at 53 °C with the other probes in 5 × SSPE (SSPE = 10 mM sodium phosphate *p*H 7.0, 0.18 M NaCl, 1 mM EDTA), 0.3% SDS and 10 μg ml^{-1} sonicated *Escherichia coli* DNA. Hybridized gels were washed in 2 × SSPE, 0.1% SDS at room temperature, in 5 × SSPE, 0.1% SDS at 53 °C for 15 min and finally in the same solution at either 59 °C (for N61-wt) or 63 °C (for the N12/13 probes) for 5 min. Gel membranes were autoradiographed for 2–4 days using intensifying screens.

hybridizes with the N13-p2 probe (data not shown) and thus contains a mutation at the same position.

Mutation to valine or aspartic acid

The use of mixed oligonucleotide probes allows the detection of the position of a mutation in a codon rather than establishing the precise mutant sequence. To analyse the exact nature of the mutations present in the N-*ras* gene of the AML transfectants, we hybridized DNAs to the individual oligonucleotide probes corresponding to the three possible mutations at the second position of codon 13. To prepare these individual probes, the labelled oligonucleotides of group N13-p2 were electrophoresed on a polyacrylamide gel (Fig. 4, insert 1), the individual bands excised and the separated oligomers further purified by electrophoresis on cellulose acetate strips (Fig. 4, insert 2).

To identify the separated oligomers, they were sequenced as described in Fig. 4 legend. The slowest-running oligomer (N13-p2/a) on the polyacrylamide gel had the sequence TTCCCAACATCACCTGCTCC and thus identifies a GAT codon 13 (Asp) in a fully matched hybrid. The second oligomer (N13-p2/b) identifies a GTT codon (Val), whereas the third and fastest-running oligomer (N13-p2/c) identifies a GCT codon (Ala). The separated oligonucleotide probes were then hybridized to *Pst*I-digested DNA from four AML transfectants. As shown in Fig. 4*A*, oligomer N13-p2/a forms a fully matched hybrid with DNA of transfectants from AML 1 and 33, whereas oligomer N13-p2/b forms a fully matched hybrid with DNAs from transfectants of AML 49 and 77 (Fig. 4*B*). The probe N13-p2/c did not hybridize with any of the transfectants (Fig. 4*C*) or with any of the separated oligomers, to control MOLT-4 DNA or to 10 genomic copies of the plasmid pAT8.8 (refs 13, 24), which contains the wild-type sequence at codons 12 and 13 (lane p). From these results we conclude that the N-*ras* gene in transfectants of AML 1 and 33 DNA contains a GAT codon 13, substituting Asp for Gly, whereas the transfectants from AML 49 and 77 contain a GTT codon 13, encoding Val. Recently, we found that AML 73 also hybridized specifically with N13-p2/b and thus contains a Val at position 13 (data not shown). The fact that the transfectant DNAs form fully matched hybrids with different members of the N13-p2 group is further evidence for the specificity of the hybridization, as each DNA now serves as a control for the other. There is no apparent correlation between the classification of the AMLs and the amino-acid substitution: AMLs 1 and 33 (Asp) were classified on the FAB scheme as M4 and M1 respectively, whereas AMLs 49, 73 and 77 (Val) were classified as M5, M2 and M4 respectively.

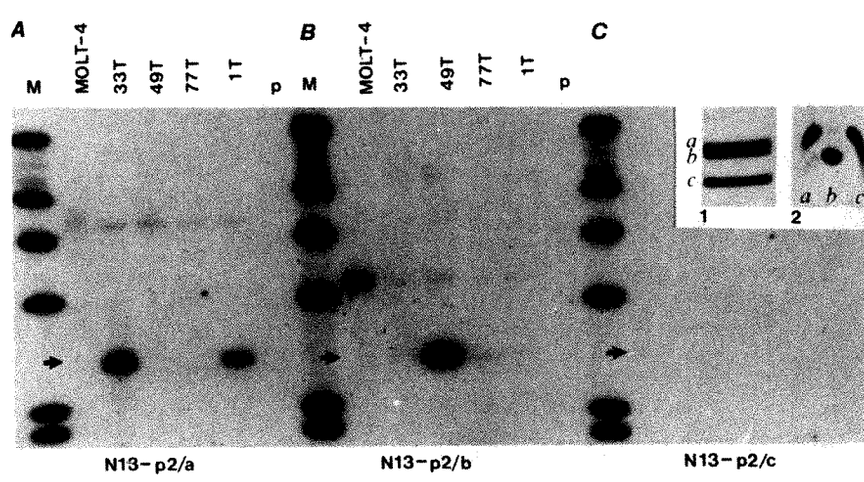

Fig. 4 Hybridization of separated N13-p2 oligomer probes to genomic DNAs of the AML transfectants. The panels are replicates of each other, with *Pst*I-digested DNAs of MOLT-4 as control and the DNAs of AML 33T, 49T, 77T and 1T. The panels were hybridized to N13-p2/a (TTCCCAACATCACCTGCTCC; panel *A*), to N13-p2/b (TTCCCAACAACACCTGCTCC; panel *B*) and to N13-p2/c (TTCCCAACAGCACCTGCTCC; panel *C*). Arrows indicate the position of the N-*ras* fragment; M, phage λ DNA digested with *Hin*dIII; p, 10 genomic copies of plasmid pAT8.8. This plasmid contains an 8.8-kb fragment of the activated N-*ras* gene HT1080 (CAA_{61}-AAA; ref. 24).

Methods. The three members of oligomers N13-p2 (*a*, *b* and *c* in inserts 1 and 2) were separated on a 20% polyacrylamide gel (mono/bis = 62.5 : 1) in 0.5 × TBE (TBE = 90 mM Tris, 90 mM boric acid, 2.5 mM EDTA) (see insert 1). To eliminate contamination, the isolated oligomers were further purified by electrophoresis on cellulose acetate strips in 7 M urea, 5% acetic acid, 5 mM EDTA *p*H 3.5 at 5,000 V (see insert 2). The fragments were eluted in 1 mM EDTA and used directly for hybridization. The sequence of each oligomer was determined by synthesizing N13-p2 with an end-labelled primer and cold deoxynucleoside triphosphates. This end-labelled probe was separated into the three members of N13-p2 and sequenced according to Maxam and Gilbert[26]. Gel separation and hybridization were as described in Fig. 2 legend.

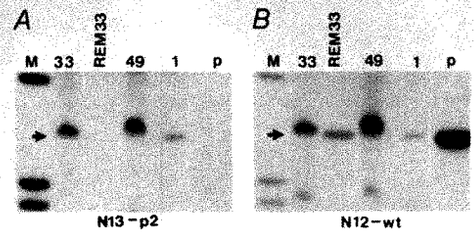

Fig. 5 Hybridization of N13-p2 (*A*) and N12-wt (*B*) oligomer probes to genomic DNA of isolated blast cells of AML patients 33, 49 and 1, and to genomic DNA of blood cells from AML patient 33 after remission (REM33). The differences in hybridization signal between the lanes result from loading differences and not from amplification of the N-*ras* gene. Arrows indicate the position of the N-*ras* band. Lane p, 20 genomic copies of the plasmid pAT8.8 containing the wild-type sequence at codons 12 and 13 (refs 13, 24). Gel separation and hybridization were as described in Fig. 3 legend.

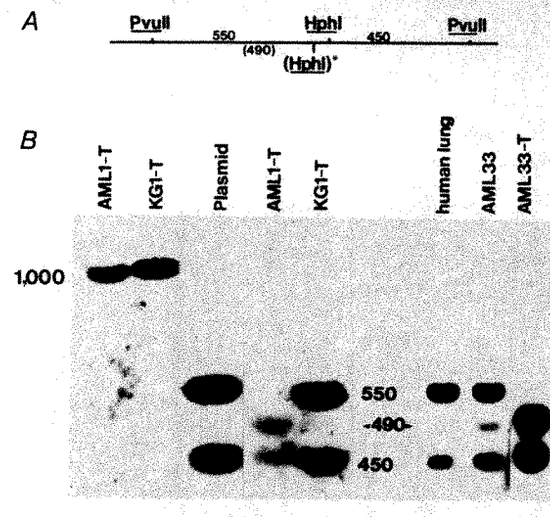

Fig. 6 *A*, Map of *Pvu*II and *Hph*I restriction enzyme sites in and around the first exon of N-*ras* to show the sizes of fragments generated after digestion of the normal N-*ras* gene and N-*ras* with Asp at codon 13. Restriction enzyme sites are taken from Brown *et al.*[13], Hall *et al.*[24] and A. Hall (personal communication). *B*, Southern blot analysis to show the altered *Pvu*II/*Hph*I fragments resulting from the presence of a new *Hph*I site generated by the Asp 13 mutation in the original leukaemic DNA from patient AML 33 and in transfectant DNAs of AML 1 and AML 33. This new *Hph*I site results in a *Pvu*II/*Hph*I fragment of 490 bp compared with 550 bp in wild-type DNA (see map).
Methods. DNA was digested either with *Pvu*II or *Pvu*II and *Hph*I, electrophoresed on a 1.4% low gelling temperature agarose gel and transferred to a nitrocellulose filter. The filter was hybridized with the nick-translated 1.0-kb *Pvu*II/*Pvu*II fragment of plasmid pAT7.8 (refs 13, 24) (see map). DNAs: pAT7.8 is a plasmid containing the *Bam*HI/*Eco*RI fragment with the first two exons of N-*ras* cloned from normal DNA[13], AML 33 is the original leukaemic sample, AML 33T a tumour derived after co-transfection into NIH 3T3 cells, AML 1T is a tumour derived from a focus isolated after transfection of NIH 3T3 cells with AML 1 DNA (note that this is a different transfectant from that used in Figs 3, 4 and 5 and contains fewer copies of N-*ras*), KG1-T (a transfectant from KG1 DNA that contains a position 12 mutation; J.W.G.J. and J.L.B., unpublished).

Somatic mutation in leukaemic cells

To exclude the possibility that the mutations at codon 13 were acquired during transfection and selection for transformed cells, the DNAs from three leukaemias were analysed. DNA was digested with *Pst*I, electrophoresed on an agarose gel and hybridized *in situ* to the oligonucleotide probes N12-wt and N13-p2. Hybridization of the gel to the mutant-specific N13-p2 oligomer group showed that all three AML DNAs hybridized, but no hybridization was detected to a sample containing 20 copies of a plasmid carrying the wild-type 12 and 13 sequences (Fig. 5*A*). Thus, the DNAs from these original leukaemic cells also contain the mutation at codon 13, eliminating the possibility that the mutations had arisen as a result of experimental manipulation.

The availability of DNA prepared from the peripheral blood of one patient (no. 33) in remission (REM33) allowed us to investigate whether the codon 13 change was present in normal cells. Figure 5*A* shows that REM33 DNA did not hybridize with the N13-p2 mutant-specific probes. As a control, we rehybridized the gel with the N12-wt probe and obtained a signal with the normal-sequence probe hybridized to REM33 DNA (Fig. 5*B*). Therefore, we conclude that this DNA (and thus the normal tissues of the patient) does not contain an altered N-*ras* gene hybridizing with N13-p2, and that the altered N-*ras* gene has arisen by somatic mutation. Hybridization with the normal-sequence probe was also obtained with the three DNAs from leukaemias, which could result from the presence of normal cells in the leukaemic sample. However, the high white blood cell counts of the leukaemic samples ($54–140 \times 10^9$ cells per l), coupled with the high proportion of cells with blast morphology (95–100%), makes it likely that the hybridization signal with the N12-wt probe is a result of the leukaemic cells containing both a normal and a mutant N-*ras* gene. The presence of amplified copies of the N-*ras* gene in some transfectants suggested that the position 13 mutations might act in concert with an increased copy number of the N-*ras* gene, but examination of the AML DNAs by Southern blotting shows no evidence of N-*ras* gene amplification (data not shown).

Restriction site polymorphism

The N-*ras* 13 mutation in AML 33 and AML 1 (Gly–Asp) changes the sequence GGTGG to GGTGA, which is the recognition site for the restriction enzyme *Hph*I. This new *Hph*I site will shorten a 550-bp *Pvu*II/*Hph*I fragment by 60 bp (see Fig. 6). We have analysed the original leukaemic DNA of AML 33 and transfectant DNAs from AMLs 1 and 33 for the presence of this extra *Hph*I site by Southern blot analysis. To that end we have compared the length of the *Pvu*II/*Hph*I fragments in these DNAs with the lengths of fragments in N-*ras* genes containing the wild-type sequence at and around codon 12 and in a codon 12 mutant (for details see Fig. 6 legend). The digestion of a plasmid, pAT7.8, containing the first and second exons of a normal N-*ras* gene[13] and of a transfectant, KG-1T, mutated at codon 12 (J.W.G.J. and J.L.B., unpublished results) generates a 550-bp *Pvu*II/*Hph*I fragment and a 450-bp *Hph*I/*Pvu*II fragment when hybridized with a probe of the *Pvu*II/*Pvu*II fragment of pAT7.8 (Fig. 6). However, when DNA from AML 33 is digested with *Pvu*II and *Hph*I, a novel 490-bp fragment, as well as the 450- and 550-bp *Hph*I/*Pvu*II fragments, is detected. The presence of both the 550-bp and the novel 490-bp fragment confirms our observation with oligonucleotide probes that this DNA contains N-*ras* genes with both a wild-type codon 13 and an Asp 13 mutation (compare Fig. 5). Southern blotting of a transfectant from AML 33 (AML33-T) and a transfectant of AML 1 (AML1-T) shows that these contain only the novel 490-bp and the 450-bp *Hph*I/*Pvu*II fragments as expected, because transfectants will contain only the mutated transforming N-*ras* allele. As a new *Hph*I site could not have been generated by a mutation in codon 12, the restriction enzyme analysis confirms the observations with oligonucleotide probes that AML 1 and AML 33 contain a codon 13 mutation of Gly to Asp.

Discussion

We have found that DNAs isolated from AML contain altered N-*ras* genes. These activated oncogenes have also been detected in three other samples of AML cells from patients[27–29]; in three AML cell lines, HL60 (ref. 28), Rc2a and KG-1 (ref. 38); and

recently in three more AML samples (D.T. and C.J.M., unpublished results). Why there should be a bias towards activation of N-*ras* genes in these leukaemias is not clear, but it is noteworthy that also in cell lines of acute lymphoblastic leukaemia, N-*ras* normally seems to be the activated *ras* oncogene[27,30]. N-*ras*, rather than the other *ras* genes, may be critically involved in the control of proliferation and differentiation of cells in the haematopoietic lineage. Alteration of this gene may then lead to the malignant state of the cells. The activation of the same *ras* oncogene in multiple isolates of similar tumours is reminiscent of findings that there is a reproducible pattern of *ras* gene activation in tumours induced by the same carcinogenic agent[31-33]. Therefore, a specific carcinogenic agent may be responsible for the N-*ras* activations in AML.

Unlike previously described examples of *ras* gene activation[3-17], we have not found mutations in codons 12 or 61. Instead, we have observed that mutations occur in codon 13, resulting in a replacement of Gly by either Val or Asp. One example of a codon 12 and a codon 61 mutation in AML cells has been noted previously[17,34] but, as only ~10–20% of malignancies seem to contain *ras* genes with mutations at codon 12 or 61 (for example, see ref. 16), the absence of codon 12 or 61 mutations in the samples we have analysed may result from the comparatively small sample size. The detection of codon 13 mutations in our samples of AML raises the question of why they have not been seen before. If codon 13 changes are restricted to AML, then they may not have been reported previously because only two mutant N-*ras* genes have been characterized from AML[17,34]. Furthermore, most of our samples were of FAB subtypes M1, M4 and M5, which have not been studied before. A restriction of codon 13 mutations to AML would imply that there is some constraint on the type of N-*ras* mutation in AML. Such a constraint could arise through the mechanism of mutation or through selection for the type of alteration in p21 protein. If codon 13 mutations are found in other malignancies, it is surprising that they have not been reported previously.

Our experience indicates that N-*ras* codon 13 mutants can be relatively inefficient in inducing foci. Although foci were detected in one laboratory with a DNA, AML 1, containing Asp 13 (ref. 38), they were not detected in another laboratory with DNA containing the same mutation, AML 33 (D.T. and C.J.M., unpublished results). This discrepancy has now been resolved by the observation that when the focus assays were kept for longer, foci induced by DNA derived from AML 33 were apparent 19–20 days after transfection but not at the usual time of examination at 15–16 days. However, foci from DNAs containing Val 13 were still not apparent even after leaving the assays for 20 days. Cells cultured from tumours resulting from co-transfection with DNAs containing the Asp 13 mutation also look more transformed than those that contain Val 13 mutants (D.T. and C.J.M., unpublished). These results are consistent with the idea that Val 13, which is an activating mutation not identified previously[18], and perhaps Asp 13 in N-*ras*, are relatively weak transforming alleles for NIH 3T3 and may be more difficult to detect than codon 12 or 61 mutations.

Our observation of multiple cases of mutations at codon 13 suggests that the activation of the N-*ras* gene at this site is an essential step in causing these AMLs. However, it is unlikely that the activation of the N-*ras* oncogene is the only step involved in the genesis of AML, because much evidence favours the argument that changes to more than one gene are involved in neoplastic transformation (see ref. 1 for review). Furthermore, specific chromosome translocations and other aberrations are associated with AML[35]. These chromosome aberrations occur at sites distinct from the 1cen–1p21 chromosomal site of N-*ras*[36] and separate aberrations are found in the different subgroups of AML. For example, a translocation, t(8;21), is found in AML M2 and an inversion of chromosome 16, inv16, in AML M4 with increased eosinophils (see ref. 35 for review). In contrast, we have found activation of N-*ras* in samples of AML from four different subgroups (M1, M2, M4 and M5); thus, the activation of N-*ras* seems to be affecting a process that is essential to all cells in the myeloid lineage, whereas the chromosome aberrations affect genes whose activities are more limited.

For the analysis of the N-*ras* mutations, we have used a set of specific oligonucleotide probes. This assay system is not only powerful in the detection of mutations in transfectant DNAs but also in the detection of specific mutations in tumour DNA. Using this assay system and the *Hph*I polymorphism generated by the Asp 13 mutation, we are currently analysing a large number of AML DNAs to gain more precise insight into the occurrence of different *ras* gene mutations in this leukaemia.

This work was supported by grants to J.L.B. and M.V. de V. from the Directorate-General of the Ministry of Welfare Health and Cultural Affairs and the Directorate-General of the Ministry of Housing, Planning and Environment of the Netherlands, to D.T. and C.J.M. from the Leukaemia Research Fund of Great Britain and to J.W.G.J. and A.C.M.S. from the Netherlands Cancer Foundation (Koningin Wilhelmina Fonds). We thank Dr D. Valenzuela for cellulose acetate strip separation of oligonucleotides, Dr R. Powles and Ms V. Sheppard for AML samples 33, 49, 73, 77 and 50, and B. Gwynne and J. Dodd for assistance with animal experiments.

Meteorites may follow a chaotic route to Earth

Jack Wisdom

Department of Earth, Atmospheric and Planetary Sciences, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

It is widely believed that meteorites originate in the asteroid belt, but the precise dynamical mechanism whereby material is transported to Earth has eluded discovery. The observational data for the ordinary chondrites, the most common meteorites, impose severe constraints on any proposed mechanism. The ordinary chondrites are not strongly shocked, their cosmic ray exposure ages are typically <20 Myr, their radiants are concentrated near the antapex of Earth's motion and they show a pronounced 'afternoon excess' (for every meteorite which falls in the morning two fall in the afternoon). Wetherill[1] concluded that these data could only be explained by an "unobserved source" of material with perihelia near 1.0 AU and aphelia near Jupiter. His subsequent, more sophisticated investigations have not changed this basic conclusion. Recently I have shown[2,3] that there is a large chaotic zone in the phase space near the 3/1 mean motion commensurability with Jupiter and that the chaotic trajectories within this zone have particularly large variations in orbital eccentricity. Since asteroidal debris is quite easily injected into this chaotic zone, it could provide Wetherill's 'unobserved source' if chaotic trajectories which begin at asteroidal eccentricities ($e < 0.2$) reach such large eccentricities that Earth's orbit is crossed ($e > 0.57$)[4]. In this report I present a numerical integration which demonstrates that at least some of these chaotic trajectories do have the properties required to transport meteoritic material from the asteroid belt to Earth. Combined with the Monte Carlo calculations which show that the resulting meteorites are consistent with all the observational constraints, the case for this chaotic route to Earth is fairly strong.

Wetherill[5,6] has completed an extensive new Monte Carlo study to determine the meteoritic yield from this chaotic zone, with some reasonable assumptions concerning the actual dynamics. He assumes that on a timescale of 10^6 years, chaotic trajectories evolve to become Earth-crossing. During much of this time the trajectories are Mars-crossing. He estimates that there is a 50% chance that the material will become Earth-crossing before Mars removes it from the chaotic zone. (It has been suggested previously[7] that meteorites could be brought to Earth from the 3/1 resonance with the assistance of Mars. The timescale for this process is, however, longer than the time for collisional disruption of meteorite-sized bodies, and fragments from any larger bodies which have taken this route will not satisfy the orbital constraints for the ordinary chondrites. It is essential, therefore, that trajectories can become Earth-crossing without the assistance of Mars.) Once the fragment becomes Earth-crossing, however, perturbations from Earth remove it from the chaotic zone in 10^4 years, the approximate duration of the Earth-crossing spikes in eccentricity. With this assumed dynamical input, the subsequent evolution is followed with the Monte Carlo method[8,9]. Wetherill's model includes planetary close encounters, secular resonances, collisional destruction in space and atmospheric ablation. He concludes that major quantities of asteroidal fragments from bodies adjacent to the 3/1 gap can be transferred to Earth. His computed flux is comparable to the observed flux of ordinary chondrites. The afternoon excess of meteorite-sized fragments obtained directly from the chaotic zone is too large, but when the fall-times of these fragments are combined with the fall-times of fragments obtained from larger objects derived earlier from the 3/1 gap, the predicted fall-time ratio agrees with the ordinary chondrite value of 2/3. Similar agreement is found for the other observable parameters.

Greenberg and Chapman[10] have also considered the consequences of this transport mechanism; while they also compute a flux of chondrites consistent with the observed flux, their physical assumptions and methods are quite different from those of Wetherill. The purpose of this letter is not to enter that debate, but to make firm the dynamics on which it is based. If trajectories in the 3/1 chaotic zone do not have the required properties the discussion is moot.

In this article 'chaotic behaviour' refers to deterministic solutions of hamiltonian systems of equations that behave erratically and show sensitive dependence on initial conditions (positive Lyapunov characteristic exponent). On theoretical grounds[11], a chaotic zone is generally expected to be associated with each commensurability in a dynamical system, though these chaotic zones are often microscopically small. Using Schubart's numerical averaging procedure[12], Giffen[13] showed that the 2/1 commensurability in the planar-elliptic restricted three-body problem is accompanied by a sizeable chaotic zone. Scholl and Froeschle[14,15] extended Giffen's work to the other principal commensurabilities; while they found chaotic behaviour near the 3/1 commensurability, they concluded that the chaotic zone was small and unimportant. In fact, there is a large chaotic zone near the 3/1 commensurability, and trajectories within this zone have the peculiar property that their orbital eccentricity can remain low ($e < 0.1$) for as long as a million years and then suddenly assume very large values ($e > 0.3$)[2,3]. The long-term evolution of a typical chaotic trajectory has bursts of low eccentricity behaviour followed by bursts of high eccentricity behaviour, each of apparently random duration. Furthermore, when the effects of phase mixing are removed, the boundaries of the 3/1 Kirkwood gap correspond, within the errors of the asteroid orbital elements, to the boundary in the phase space of the chaotic zone. The 3/1 Kirkwood gap can be explained entirely by removal of the highly eccentric chaotic orbits and the also highly eccentric quasiperiodic librators by collisions with Mars and, as reported here, Earth.

These discoveries depended on the development of a new 'mapping' technique for studying the long-term evolution of trajectories near commensurabilities that is approximately 1,000 times faster than all previous methods. This method is approximate (as are the methods used in earlier studies), but the essential features of the picture presented above have been verified by conventional numerical integrations of the exact equations of motion for the planar-elliptic restricted three-body problem[3]. In particular, the width of the chaotic zone is in perfect agreement with that found using the mapping method. Even at eccentricities as high as 0.4, the trajectories using the mapping and the exact solutions are in good qualitative agreement, even though fourth-order terms in eccentricity are neglected in the disturbing function. Independent investigation has confirmed this qualitative agreement[16].

In the planar-elliptic problem, the eccentricity of chaotic trajectories which begin at asteroidal eccentricities ($e < 0.2$) seems to be limited to values <0.5; this is large enough for the trajectories to be Mars-crossing but not Earth-crossing. However, in the three-dimensional elliptic problem, chaotic trajectories computed with a mapping reach much larger eccentricities, large enough to be Earth-crossing ($e > 0.57$). Now the approximations used to derive the mapping are certainly invalid at such large eccentricities, but the success of the planar mapping at eccentricities as large as 0.4 encourages one to take these high eccentricities seriously. The actual eccentricity limit can be determined only by numerical integration of the exact equations of motion. Such integrations are time-consuming, but the answer is vital to our understanding of the origin of meteorites.

One approach to this problem is simply to integrate a chaotic trajectory until it reaches Earth-crossing eccentricities. Experience with the mapping, however, indicates that this may take several million years. Furthermore, not all chaotic trajectories are equivalent; there is an integral which divides the chaotic zone into a one-parameter family of chaotic zones. Some

of these may have Earth-crossing trajectories and others not; we do not accurately know the extent of the eccentricity variations for any chaotic trajectory. It might then be necessary to integrate several chaotic trajectories for several million years to find the Earth-crossing route. This approach is not practical without a dedicated computer. Instead, I have sought, by trial and error, trajectories which begin near that point in the phase space where transitions from low eccentricity behaviour to high eccentricity behaviour occur, with as much guidance from the mapping as I have been able to glean. (While the mapping does give the correct qualitative behaviour, the correspondence is not precise enough to directly determine initial conditions.)

The numerical integrations include the Sun, the four major planets and a test body. Pluto is clearly not important because of its small mass. The inner planets are included with the Sun. I am attempting to show that the long-term evolution of a chaotic trajectory without close planetary encounters will bring material within the influence of Earth's gravitational field. It seems fair to ignore Earth until this is the case. The neglect of Mars perturbations is clearly more serious. I argue that Mars substantially affects the solution only during close encounters and that these close encounters may be taken into account after the fact in a statistical manner, much as Wetherill[6] has done. (His approach may not be entirely satisfactory. As mentioned previously, there is a family of chaotic zones, not just one. Minor encounters with Mars will be sufficient to cause a shift from one member of this family to another without removing the trajectory entirely from the chaotic zone. Several such shifts may occur before Earth is reached. Nevertheless, such trajectories would essentially be injected directly into Earth's control. Thus this synergism between Mars perturbations and chaotic dynamics is qualitatively different from previously proposed mechanisms[7] that rely on Mars perturbations to assist in the transfer of material from the Kirkwood gaps.)

The integrations were performed in equatorial rectangular coordinates referred to the mean equinox and equator 1950.0. The origin was the baricentre of the Sun and four inner planets. The unit of time was 40 mean solar days; the origin of time was taken to be 1982 August 19.0 (JD 2,445,200.5). The extrapolation algorithm of Bulirsch and Stoer[17] was used to perform the integrations. The relative accuracy per integration step was chosen to be 10^{-11}; the variable integration step was of the order of 1 yr. The twelfth-order Cowell method used by Cohen *et al.*[18] in their 1-Myr integration is less satisfactory when the eccentricities are large as in the integrations reported here. The initial conditions for the major planets were obtained from those used by Cohen *et al.* by numerical integration from their origin of time (JD 2,430,000.5) to mine. Their initial conditions for the major planets were in turn taken from the work of Eckert *et al.*[19], where the equations of motion can be found. No effort has been made to correct the initial conditions to properly account for my removal of Pluto. Because of the large Pluto mass used by Eckert *et al.* this introduces a relative discrepancy

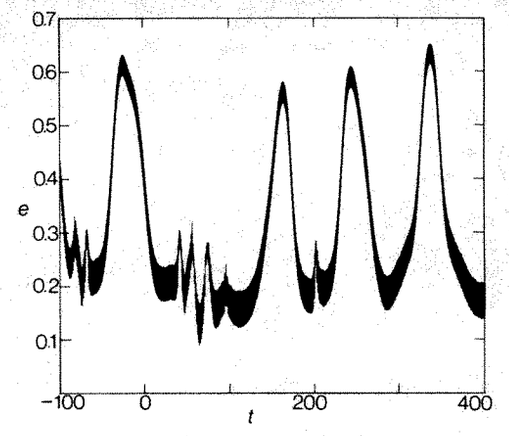

Fig. 1 The eccentricity (e) as a function of time (t, in millennia) plotted for the chaotic trajectory, which at times is deep in the asteroid belt (when $e < 0.15$) and at other times is strongly Earth-crossing ($e > 0.6$). The time origin is 1982 August 19.0.

of one part in a million in the Cartesian coordinates just in the integration from their origin of time to mine. (I have verified, however, that when Pluto is included the program satisfactorily reproduces the tables of Eckert *et al.*[19].) The accuracy of these numerical integrations was tested directly by integrating the planets forward with one test meteoroid 170,000 years, and then integrating them back to the time origin with a different meteroid on an independent trajectory. Since the time step chosen by the integrator is mainly determined by the eccentricity of the meteoroid, these two integrations are completely independent. The initial conditions of the major planets were reproduced to one part in 10^4. The skeleton of the integration is thus adequately represented.

It is well known that chaotic trajectories are difficult to follow precisely. In a chaotic zone neighbouring trajectories separate exponentially with time, and consequently so do round-off errors. Fortunately, the rate of this exponential separation is rather small for the 3/1 chaotic zone[3]; nevertheless, even a small exponential growth of errors is unbeatable. Now it has been argued[20] that even though any particular trajectory cannot be followed precisely, the qualitative behaviour of the trajectory will be correct if reasonable care is taken and furthermore that a true trajectory can be found which shadows the computed trajectory. This is not as wild a claim as it may seem, for it has been proven for the special class of Anosov dynamical systems. It is probably not strictly true for Hamiltonian systems in general, but most people who study chaotic behaviour in dynamical systems believe that it is practically true. The actual rate of separation of nearby trajectories in the 3/1 chaotic zone allows strict confidence to be placed in segments of 80,000 years[3]. Over longer times we may only hope that some true trajectory shadows

the computed trajectory. In any case 80,000 years is long enough to cover the most interesting behaviour.

I have made five numerical integrations, each spanning ~500,000 years. The initial conditions were chosen in the chaotic zone as determined by the three-dimensional mapping. The initial eccentricity for the first four was 0.15, the mean eccentricity of the asteroids; for three of these the resulting peak in eccentricity was between 0.5 and 0.54, insufficient for Earth-crossing. Earth's maximum aphelion occurs at 1.07 AU (ref. 21); for semimajor axes near the 3/1 commensurability ($a \approx 2.5$ AU) an eccentricity of 0.57 is required to just graze this distance. The results of the first three integrations were encouraging but not sufficient. The fourth integration, however, reached an eccentricity of 0.564 after 170,000 years. Its initial conditions (JD 2,445,200.5) were: semimajor axis $a = 0.4816 a_J$, eccentricity $e = 0.15$, inclination = 5°, mean anomaly $M = 180° + 3M_J$, longitude of perihelion $\varpi = \varpi_J$ and longitude of ascending node $\Omega = \varpi_J$. These elements are heliocentric osculating elements relative to the equinox and ecliptic 1950.0, and the subscript J refers to Jupiter. These initial conditions are on the representative plane[3]. This trajectory came so close to Earth-crossing (0.01 AU) that it appeared possible to change the coordinates enough to make it Earth-crossing and still remain in the chaotic zone. The first attempt to do this was, however, unsuccessful. The resulting trajectory was clearly quasiperiodic in nature. With a somewhat smaller increase in eccentricity, however, the route to Earth was found.

The initial conditions for this chaotic trajectory are given in Table 1. The trajectory was integrated both forward and backward in time from that point. The eccentricity as a function of time (in millennia) is shown in Fig. 1; the peak in eccentricity occurs near $t = 340{,}000$ yr with the value $e_{max} = 0.652$; the minimum perihelion distance is $q_{min} = 0.861$ AU, which is strongly Earth-crossing. The peak near $t = -20{,}000$ yr has $e_{max} = 0.632$ and $q_{min} = 0.910$ AU. The minimum in eccentricity occurs near $t = 60{,}000$ yr during a short burst of low eccentricity behaviour with the value $e_{min} = 0.089$; this value is lower than the mean eccentricity of the asteroids. The semimajor axis remains between 2.47 AU and 2.53 AU as expected. The inclination to the ecliptic varies between 1° and 8° in a way that is not obviously correlated with the eccentricity. The behaviour of the resonant argument $\sigma = l + 2\varpi - 3l_J$, where l is the mean longitude, is very complicated. During the eccentricity spikes it librates about a slowly varying centre which makes one revolution during the spike; during the low eccentricity bursts it circulates. The behaviour of the semimajor axis is correlated with the resonant argument: during the eccentricity spikes the semimajor axis oscillates across its full range of variation, but during the low eccentricity bursts it alternately oscillates on one side or the other of the centre of that range. This behaviour is familiar from the mapping studies, and consistent with the qualitative picture of these bursts presented previously[3]. The maximum Lyapunov exponent for this chaotic trajectory is $\lambda \approx 10^{-3.8}\ \mathrm{yr}^{-1}$.

The peak in eccentricity that occurs near 170,000 years, near our starting point, has $e_{max} = 0.583$ and $q_{min} = 1.034$ AU. Since q_{min} is less than Earth's maximum aphelion of 1.07 AU I was initially satisfied that this trajectory was indeed Earth-crossing; on closer examination this turned out not to be the case. I first checked that the argument of perihelion (the angle between the longitude of the ascending node and the longitude of perihelion was satisfactory. It turns out to be correlated with the peaks in eccentricity, and to be ideally placed for Earth-crossing (near zero). If it had been near 90° when the eccentricity was large, then Earth's orbit would not intersect the meteoroid's orbit—the meteoroid's orbit would have crossed the ecliptic near Mars. However, a more subtle avoidance mechanism was operative. During the peaks in eccentricity the longitude of perihelion aligns with Jupiter's longitude of perihelion. Although it is not commonly known, Earth's perihelion is also correlated with Jupiter's perihelion. Earth's maximum aphelion distance always occurs when the perihelia of Earth and Jupiter are aligned. Thus, if the meteoroid and Earth are both near their maximum eccentricities, their orbits are aligned so that no crossing occurs. It is a simple matter to calculate from Brouwer and van Woerkom's solution[22] of the secular motions of the planets that when Earth's perihelion is anti-aligned with Jupiter's perihelion, Earth's maximum aphelion is only 1.031 AU. During this peak the meteoroid came quite close to Earth, but "An inch is good as a mile". Nevertheless, the other peaks in eccentricity are strongly Earth-crossing and no avoidance mechanism is operative.

I thank S. J. Peale, G. W. Wetherill and C. C. Counselman for helpful conversations and A. Levine for computational assistance. Poorly graphitized carbon as a new cosmothermometer for primitive extraterrestrial materials

Frans J. M. Rietmeijer*

* Solar System Exploration Division and † Microbeam Inc., Mail Code SN4, NASA Johnson Space Center, Houston, Texas 77058, USA

The presence of carbon in primitive extraterrestrial materials has long been considered a useful indicator of prevailing geochemical conditions early in the formation of the Solar System. A recent addition to the suite of primitive materials available for study by cosmochemists includes particles collected from the stratosphere called chondritic porous (CP) aggregates[1]. Carbon-rich CP aggregates are less abundant in stratospheric collections and contain many low-temperature phases (such as layer silicates) as minor components[2,3]. We describe here the nature of the most abundant carbon phase in a carbon-rich CP aggregate (sample no. W7029*A) collected from the stratosphere as part of the Johnson Space Center (JSC) Cosmic Dust Program[4]. By comparison with experimental and terrestrial studies of poorly graphitized carbon (PGC), we show that the graphitization temperature, or the degree of ordering in the PGC, may provide a useful cosmothermometer for primitive extraterrestrial materials.

A detailed analytical electron microscope (AEM) investigation of CP aggregate W7029*A has established that parts of this aggregate experienced nominal flash-heating no higher than

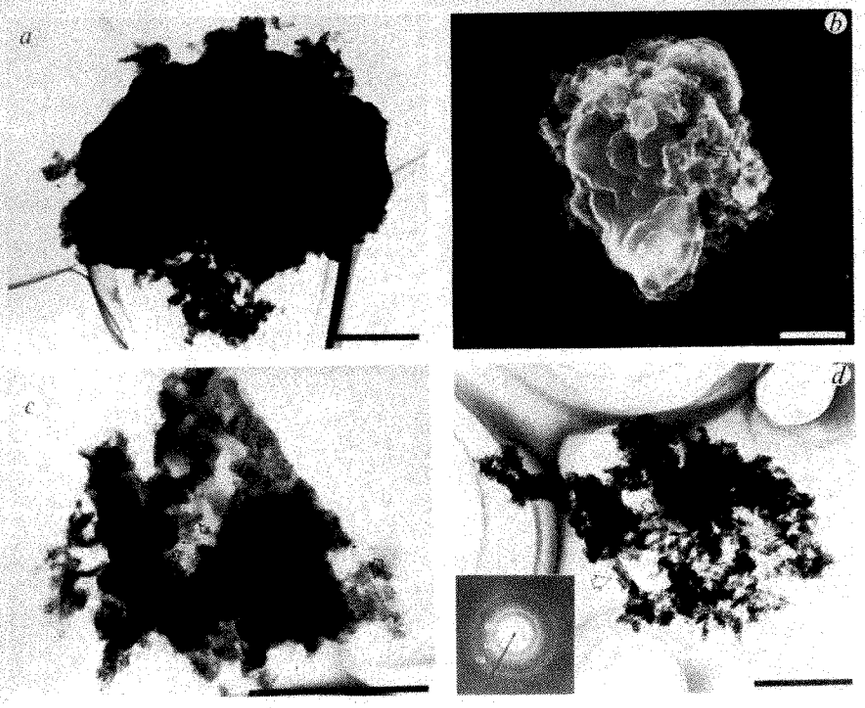

Fig. 1 Examples of carbon particles in CP aggregate W7029*A. *a*, TEM image of clumped carbon particle with granular areas along the margin. *b*, SEM image of the same carbon particle as *a*, but tilted to show individual plates and granular strings (arrowed). *c*, TEM image of granular particle showing two-dimensional fibrous domains (arrowed). *d*, TEM image of an open, fluffy granular cluster with three small sheets (arrowed) and its typical SAED pattern of diffuse rings (inset). Scale bars, 0.5 μm.

300–400 °C during atmospheric entry and that terrestrial contamination of the aggregate was not significant[3]. The fluffy morphology and chondritic bulk composition of CP aggregate W7029*A, as well as unique mineralogy, are reliable indicators of its extraterrestrial origin[2,3]. A modal analysis of 224 grains from this CP aggregate shows that ~45% are carbon-rich phases and ~30% are low-temperature phases (such as layer silicates, geothite and sulphides). Further details on the mineralogy of minor phases in CP aggegate W7029*A, as well as collection, curation and processing procedures at the JSC Curatorial Facility are given elsewhere (refs 3, 5 and refs therein). Data on CP aggregate W7029*A were obtained with a JEOL 100CX AEM operating at 100 kV and equipped with a Princeton Gamma Tech System IV energy dispersive spectrometer (EDS). Electron energy loss spectra (EELS) were collected with a Gatan spectrometer attached to a Philips EM 420 AEM operating at 120 kV. The interlayer spacings obtained from calibrated electron diffraction patterns and listed in Table 1 for CP aggregate W7029*A have a relative error of 1%.

Carbon-rich particles in CP aggregate W7029*A form separate clump-like masses. (EDS analyses of 65 clumped masses are consistent with materials in which elements with atomic number >10 are absent. In addition, electron energy loss spectroscopy of selected clumped masses confirmed the presence of carbon only.) Carbonaceous material with similar morphologies have been described in two CP aggregates containing silicate and magnetite platelet grains[6]. Figure 1*a*, *b* shows transmission and scanning electron microscope (TEM and SEM) images of a typical carbon particle in CP aggregate W7029*A. The clumps of carbonaceous material range in size from 0.2×0.3 μm to 1.5×2.0 μm. These clumped masses appear to consist of stacked sheets with lobate circumferences and may have a ragged topography (Fig. 1*b*). Individual sheets may be decorated by fine-scale (0.01–0.05-μm diameter) granular carbonaceous material. These granules may coalesce to form decorative strings around and up on individual sheets, or may form larger granular clusters with an open, fluffy texture (Fig. 1*c*, *d*). Within these granular clusters, small sheets are occasionally observed (see Fig. 1*d*). TEM images of the clumped masses show two-dimensional fibrous domains (100–1,400 Å long and 45–60 Å wide), open, randomly oriented loops and subcircular structures ~150–500 Å in diameter. Selected area electron diffraction (SAED) patterns of the granular clusters from CP aggregate W7029*A show broad, diffuse rings (inset, Fig. 1*d*) and have 002, 10*l* and 11*l* interlayer spacings consistent with PGC[7]. In addition, the range and type of morphologies observed for the carbon phases in CP aggegate W7029*A are similar to those observed for PGC formed by carbonization, that is the removal of oxygen and nitrogen, and subsequent graphitization of hydrocarbons[8,9].

Other primitive extraterrestrial materials, particularly the carbonaceous chondrites, contain variable amounts of carbon

Table 1 Interlayer spacing, dimensions of the graphite component and fraction of ordered layers in PGC in three carbonaceous chondrites and CP aggregate W7029*A

		Carbonaceous chondrites		
	CP aggregate W7029*A	Orgueil (CI)	Cold Bokkeveld (CM)	Allende (CV)
d_{002} spacing (range) (Å)	3.50 (3.47–3.53)	3.8 (3.5–4.1)	3.6 (3.4–3.9)	3.47 (3.39–3.5)
Fibres L_a (Å)	<100–1,400	60–200	100–420	190–270 150–1,000*
Fibres L_c (Å)	45–60	20–40	35–140	60–100
Polygonal and subcircular structures (Å)	150–500	2,000–3,500	1,500–2,000	100–150*
Fraction of ordered layers (p)	0	0	26	35

Meteorite data are from refs 7, 10* and CP aggregate W7029*A data from the present study. The number of samples for Orgueil, Cold Bokkeveld meteorites and CP aggregate W7029*A is one; for the Allende meteorite five samples are used. In each sample, a larger number of individual particles have been studied (for example, 65 in the aggregate). Note that the true length of fibrous crystallites (L_a) may be greater because lattice fringes can only be observed if the graphite basal reflection (d_{002}) is parallel to the incident electron beam. L_c, the width (= thickness) of fibrous crystallites.

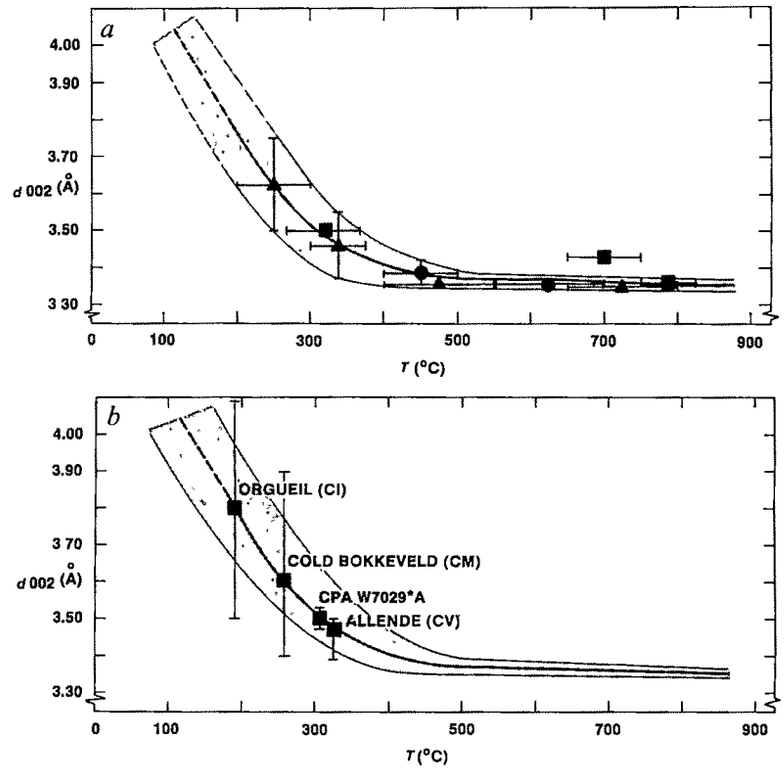

Fig. 2 *a*, Average d_{002} interlayer spacing (Å) in naturally occurring poorly graphitized carbon in terrestrial metamorphic rocks plotted against temperature (°C). The shaded area denotes uncertainty in the data Sources. ●, ref. 11; ■, ref. 13; ▲, ref. 14. *b*, d_{002} interlayer spacing in PGC from carbonaceous chondrites and from CP aggregate W7029*A plotted on the curve for PGC in terrestrial metamorphic rocks.

phases. AEM studies of acid residues of the Allende CV meteorite show that carbon phases form as tangled, fibrous (graphitic) crystallites, or aggregates of crystallites, in a featureless (possibly amorphous) matrix[10]. Subcircular to polygonal concentric structures with the graphite basal plane spacing were also observed[10]. SAED patterns from carbonaceous material in the Orgueil (CI), Cold Bokkeveld (CM) and Allende (CV) meteorites have been obtained by Lumpkin[7]. These SAED patterns typically show broad rings corresponding to the 002, 101 and 111 reflections of turbostratic carbon, or PGC.

The average d_{002} interlayer spacings for each of these primitive materials and for CP aggregate W7029*A are listed in Table 1. For the Orgueil, Cold Bokkeveld and Allende meteorites the size of fibrous crystallites increases uniformly with decrease in average d_{002} interlayer spacing (Table 1). In addition, the diameter of subcircular to polygonal concentric structures decreases from the Orgueil to Cold Bokkeveld to Allende meteorite. In Table 1, all four classes of primitive material show distinct signatures for the PGC. Our compilation of data suggests that a parameter related to the environment of formation may be responsible for the variation in d_{002} spacing, size and morphology of PGC in all four primitive extraterrestrial materials.

There exists a large body of data on the processes of carbonization and graphitization[8,9], in both experimental conditions and within natural systems[11]. These data provide further insight into the probable formation conditions for PGC in CP aggregate W7029*A and selected carbonaceous chondritic meteorites. The d_{002} interlayer spacing is a characteristic structural feature of poorly graphitized carbons which can range from values of 4.8 to 3.44 Å (the average interlayer spacing of extensive, randomly stacked graphitic layers) to 3.354 Å, the value typical of fully ordered hexagonal graphite[8]. Experimental work has shown that this variation in d_{002} interlayer spacing is temperature-dependent. Thus, with heat-treatment temperature the d_{002} interlayer spacing steadily decreases from 4.8 to 3.44 Å (ref. 8). The sizes of tangled graphitic fibres are directly related to the formation temperature of poorly graphitized carbon[9] and increase with increased heat-treatment temperature and/or time. These experiments[8,9] are of short duration and use pure starting materials. In all experiments, the extent of graphitization of carbon compounds is strongly influenced by the presence of a catalyst[12].

A similar temperature-dependency for d_{002} interlayer spacing PGC can be observed in natural terrestrial environments. Graphitization in terrestrial rocks may occur over long periods of time (millions of years) (long duration of heat-treatment) and may also be influenced by an active fluid phase, lithostatic pressure or the presence of catalytic minerals (such as silicates and carbonates)[11]. Owing to these influences, in general, the temperature recorded by graphitization of PGC in a metamorphic rock[11] will be lower than that determined by experiments with pure starting materials[8].

Both X-ray diffraction and AEM have been used to study graphitization in terrestrial metamorphic rocks[11,13-15]. Using data collected with both techniques, we have plotted (Fig. 2*a*) the average d_{002} interlayer spacings for PGC from a suite of metamorphic rocks against their peak metamorphic temperatures. In all cases, peak metamorphic temperatures used in Fig. 2*a* are those given by the original authors[11,14] except for the sequence described by French[13]. For these data points, we estimated peak metamorphic temperatures using recently published petrological data for these contact-metamorphosed Precambrian iron formations[16-19]. The ranges of d_{002} interlayer spacings and peak metamorphic temperatures for each data point are represented by vertical and horizontal error bars, respectively, in Fig. 2*a*. As we show, the average d_{002} interlayer spacing for PGCs in terrestrial metamorphic rocks decreases with increased peak metamorphic temperature up to ~450 °C. Above this temperature the carbon phase may become fully ordered graphite.

The mean apparent interlayer spacing (d_{002}) can be related to the degree of order (degree of graphitization), or the fraction of sp^2 carbon layers in PGC. For synthesized PGCs, an expression relating the mean apparent interlayer spacing and the fraction, p, of ordered layers may be written as $d(002) = 3.44\text{-}0.086(1-p^2)$ (ref. 20).) Using this equation, we have listed in Table 2 the calculated degree of order for each natural occurrence used to construct Fig. 2*a*. This tabulation indicates that the degree of order determined from average d_{002} values does not vary uniformly with estimated peak metamorphic temperatures. However, we can understand this variation in degree of order for terrestrial rocks if we consider the duration of peak metamorphic heating as well as the peak metamorphic

Table 2 Interlayer spacing and estimated peak metamorphic temperature for PGC from terrestrial metamorphic rocks

d_{002} spacing (Å)	Peak metamorphic temperature (°C)	No. of observations	Degree of order
Poorly graphitized carbon			
3.75–3.50	200–300 (14)		0
3.55–3.37	300–375 (14, 23)	27 (14)	0–57
3.36–3.35	400–500 (14, 23)		74–80
3.50	320±50 (16–19)	8 (13)	0
3.43	650–750 (16–19)		6
3.42–3.36	400–500 (11)	8 (11)	12–74
Fully ordered graphite			
3.35	600–800 (14, 23)	8 (14)	100
3.36	750–825 (16–19)	8 (13)	100
3.36	500–700 (11)	8 (11)	100

The numbers in parentheses refer to the source of data. Data points from refs 11, 14 are regionally metamorphosed rocks; data points from ref. 13 are for contact metamorphic rocks. References 16–19 and 23 are used to estimate peak metamorphic temperatures for contact metamorphic rocks in ref. 13 and for regionally metamorphic rocks in ref. 14.

temperature. For example, graphitization takes place in contact metamorphic rocks at ~1,000 °C. However, for regionally metamorphosed rocks a comparable degree of graphite order occurs at ~600 °C if the duration of metamorphic heating is at least 1,000 yr (ref. 11). For metamorphic rocks at lower temperatures, kinetic factors tend to dominate the graphitization process and the range of values for the d_{002} interlayer spacing may reflect a random statistical effect of non-uniform degrees of order within a given sample. Thus, it is appropriate to use the average d_{002} interlayer spacing for individual samples to derive graphitization temperature, or degree of order.

The curve in Fig. 2*a* shows the relationship between the average d_{002} interlayer spacing and peak metamorphic temperature for PGC in terrestrial metamorphic rocks. In Fig. 2*b*, the values of the d_{002} interlayer spacing for selected primitive extraterrestrial materials are superimposed on this curve for terrestrial occurrences. We then estimate graphitization temperatures for the carbonaceous chondrites at ~190 °C (Orgueil), ~260 °C (Cold Bokkeveld) and ~335 °C (Allende) and for CP aggregate W7029*A at ~315 °C. The inverse relationship between sizes of fibrous crystallites and diameters of subcircular to polygonal concentric structures[9] in the carbonaceous chondrites (Table 1) is also compatible with higher temperatures for Allende compared with the Orgueil meteorite.

Graphitization temperatures derived from Fig. 2*b* are higher than the calculated accretion temperatures for carbonaceous chondrites: <42–87 °C for C1 and CM chondrites, <127 °C for CV chondrites[21]. Graphitization in these meteorites may be reasonably related to post-accretion processes, as graphitization is an irreversible process[8] and the temperatures obtained from Fig. 2*b* are probably minimum estimates. The curve in Fig. 2*a* probably averages the effects of all parameters which influence graphitization of poorly graphitized carbons on a geological timescale. The presence of active catalytic phases will lower the graphitization temperature[11]. However, unless catalytic activity in these primitive extraterrestrial materials was more pronounced than in the terrestrial occurrences used for Fig. 2*a*, the curve in Fig. 2*b* represents graphitization temperatures for PGCs in these extraterrestrial materials. If catalytic activity in these meteorites and CP aggregate W7029*A was indeed more dominant than is assumed for the curve in Fig. 2*b* all data points would shift towards lower temperatures.

We have shown that graphitization temperatures in terrestrial rocks may be a useful guide to the interpretation of graphitized carbon occurrences in extraterrestrial materials. The degree of graphitization in a suite of primitive extraterrestrial materials follows a simple trend which may be related to the duration and temperature of peak metamorphic heating during formation. Graphitization temperatures recorded in this suite of extraterrestrial materials and derived from terrestrial trends are consistent with metamorphic temperatures experieneced after condensation of the solar nebula but early in the history of the Solar System. Further investigation of graphitization in extraterrestrial materials may provide useful constraints on the formation of parent bodies for primitive chondrites and CP aggregates[22].

We acknowledge Dave McKay for a review of the manuscript and for access to the electron microscope facilities at NASA/JSC; and Dr C. T. Pillinger for a critical review. Richard McConnville and John Fahey of Philips Electronic Instruments Inc. are acknowledged for assistance with EELS data. We thank GeorgAnn Robinson and Fleur Rietmeijer-Engelsman for technical assistance. Partial support for this work was provided by NASA contract NAS9-17005 to Microbeam Inc. Institut de Recherches sur la Catalyse, CNRS, 2, Ave Albert Einstein, 69626 Villeurbanne Cedex, France

The use of stabilized zeolite Y as a cracking catalyst for converting petroleum into gasoline, fuel oil and petrochemical feeds is widespread[1]. During the stabilization process, when the ammonium-exchanged form of zeolite Y is heated to high temperatures, aluminium is extracted from the zeolite framework[1–3]. The nature of this non-framework aluminium has been of considerable interest because of its possible influence on the zeolite acidity and thermal stability. Indirect information on the nature of the non-framework Al (NFA) has been obtained from infrared spectroscopy, X-ray diffraction, absorption and nuclear magnetic resonance (NMR) studies. To obtain further knowledge of the NFA species, we have now performed radial electron distribution studies of H–Y and H–Y dehydroxylated in vacuum and steam. These studies suggest that the non-framework Al species probably contain edge-shared octahedral $Al_m(O,OH)_n$ chains similar to those found in $NaAlSi_2O_6$ (jadeite), $CaAl_2(OH)_4SiO_4$ (chantalite) and $Al_2(OH)_2TeO_3SO_4$.

The loss of Al from the framework and the development of octahedral Al is evidenced by (1) infrared spectroscopy from

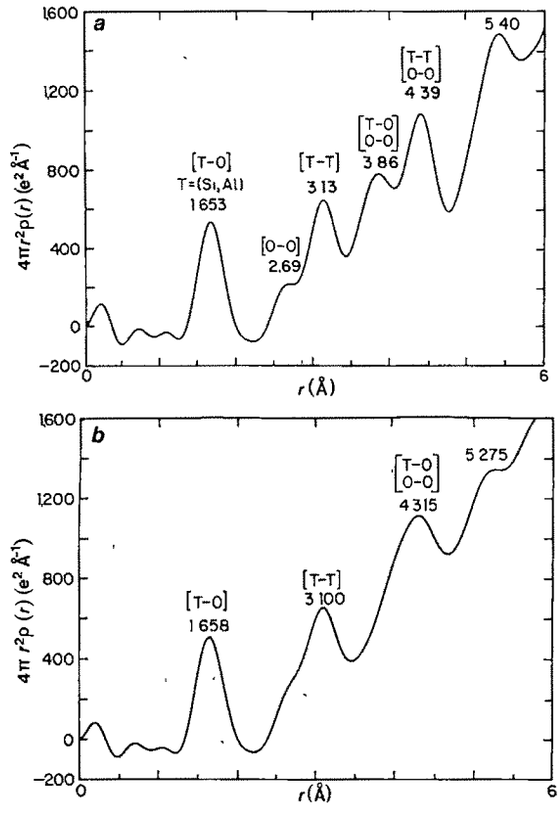

Fig. 1 Experimental RDFs for HY (*a*) and HY-DH (*b*) Both in vacuum; temperatures 300 °C (*a*) and 650 °C (*b*).

shifts in the infrared (Si, Al)-oxygen (T-O) stretching frequencies[4-9]; (2) X-ray fluorescence spectroscopy from shifts of the SiKβ and AlKβ lines[10-13]; (3) X-ray diffraction from the decrease in cell dimensions[5,7,8,14]; (4) X-ray structure analyses of dehydroxylated Y[14]; (5) ^{29}Si-NMR from increases in the Si/Al ratios[15-17]; and (6) ^{27}Al-NMR from observation of spectra arising from octahedral Al species (refs 18-20 and P. A. Jacobs *et al.*, in preparation). Infrared spectra in the OH region frequently show weak bands which appear after dehydroxylation. These bands are generally believed to result from OH groups associated with either the NFA species[21] or vacancies created during the removal of Al[5,22,23]. There has been no unequivocal identification of these bands, but the species $Al(OH)^{2+}$, $Al(OH)_2^+$, AlO^+, $[Al_2O_2OH]^+$, $[Al_2O]^{4+}$ and $Al(OH)_3$ (refs 11, 14, 21, 24-29) have been proposed. Recently, ^{27}Al-NMR studies have indicated that the NFA species in zeolite Y contain octahedrally coordinated Al and are located in large cavities after deammoniation at 300 °C and are distributed in both the large cavities and the sodalite cages after treatment at 500 °C[20]. A distinction between low-condensed mobile NFA species formed at 300-500 °C under shallow-bed conditions and higher-condensed, immobile species formed at 500 °C under deep bed or moist conditions was made by Freude *et al.*[19] and Raatz *et al.*[13].

One sample of Na-Y for use in vacuum dehydroxylation was exchanged eight times with 1 M NH_4Cl to yield NH_4-Y-containing 0.99% Na (dry basis). Activation was carried out in a U-shaped quartz cell containing two 5-cm^2 frits. NH_4-Y (5 g) was heated in flowing O_2 (5 °C min^{-1}) from 25° to 300 °C to eliminate all hydrocarbons. The sample was then evacuated and held for 15 h at 300 °C to obtain H-Y. The quartz cell was opened in a glove box where 1 g of zeolite was transferred to a controlled atmosphere cell used to collect X-ray intensity data. The zeolite powder was pressed into a rectangular cavity in the inside of the back of the X-ray cell which was filled with Ar before removal from the glove box. Vacuum-dehydroxylated Y (HY-DHV) was prepared by transferring the H-Y used for data collection back to the U-tube, heating the sample to 650 °C for 6 h in a 10^{-5} torr vacuum. To minimize possible de-alumination by escaping NH_3 and H_2O, care was taken to heat the sample in a shallow-bed (1 mm thick) configuration and to increase the temperature slowly from 25 to 650 °C under vacuum. The sample was then retransferred to the X-ray sample holder in the glove box. A further sample of NH_4-Y containing 2.2% Na was prepared for steam dehydroxylation. NH_4-Y was heated under 100% H_2O at 600 °C, re-exchanged with NH_4Cl and reheated in 100% H_2O at 890 °C to give steam-dehydroxylated Y (HY-DHSt)[30].

Table 1 RDF spectra for non-framework Al species in HY-DH

d(Å)		
HY-DHV	HY-DHSt	Assignment
—	1.86	Al-O_t
—	2.10	Al-O_{br}
2.87	2.91	Al-Al, O-O
3.39	3.35	Al-O
4.12	4.17	Al-O
4 82	4.84	Al-Al, O-O, Al-O
5 79	—	Al-O, O-O

The X-ray diffraction patterns were recorded with a stabilized Philips diffractometer using a 2,400-W tube with molybdenum anode (λ(MoKα) = 0.710 Å) using a technique described earlier[31]. The radial distribution functions (RDFs) were calculated by Fourier transformation of the scaled intensities as described previously[32].

The calculations of the RDFs of the Al_3O_{14} clusters were made using the computer program RADMOR developed by D'Antonio and Konnert[33] after modification to run on a VAXS 11/780 computer. The program is described in detail in ref. 33 but we include above a brief description of the quantities calculated and parameters used in our calculations.

RADMOR calculates the following expression:

$$4\pi\rho(r) = \frac{1}{r}\sum_{i=1}^{n}\sum_{j=1}^{m}\frac{w_i w_j \bar{f}_i \bar{f}_j \exp[-(r-r_{ij})^2/2\sigma_{ij}^2(r)]\Delta r}{r_{ij}\sigma_{ij}(r)\sqrt{2\pi}}$$

where $4\pi\rho(r)$ is the probability, weighted by the scattering power of the atomic pair ij, $(f_i f_j)$, of finding atoms j in a shell of thickness Δr and radius r_{ij} from origin atoms i. w_i is the occupancy of atom i, $f_i = f_i(s=0)/[f^2(s=0)]^{1/2}$ where—$s = 4\pi \sin\theta/\lambda$—is the reduced, scattering angle independent, scattering factor for atom i, r_{ij} is the distance between atoms i and j and $\sigma_{ij}(r)$ includes both the r.m.s. displacement along r_{ij} and positional disorder. The first sum is carried out over the *n* atoms in the asymmetric unit for a crystalline material. The second sum is carried out over the *m* atoms in the structure that are separated from an atom in the asymmetric unit by less than the maximum distance selected for the calculation. For crystalline materials, space group transformations and unit cell translations are used to generate the atom positions in the second sum.

The pair correlation function, $G(r)$, for a spherical region of radius *t* is defined as:

$$G(r) = 4\pi r[\rho(r)/\varepsilon(r, R) - \rho_0]\varepsilon(r, t)$$

where for spherical particles $\varepsilon(r, R)$ is given by:

$$\varepsilon(r, R) = 1.0 - \frac{3}{4}\left(\frac{r}{R}\right) + \frac{1}{16}\left(\frac{r}{R}\right)^3 \quad \text{for } r \leq 2R$$

$$\varepsilon(r, R) = 0 \quad \text{for } r \geq 2R$$

When the input model is an infinite crystal, $\varepsilon(r, R) = 1$ and $\varepsilon(r, t)$ corrects for the fall-off in scattering near the diameter of a finite spherical particle. *R* is radius of model fragment.

The disorder parameters $\sigma_{ij} = 0.05$ at 1.5 Å and 0.19 at 10 Å were based on experimental values for SiO_2 glass obtained by Konnert and Karle[34] and Konnert *et al.*[35]. The RDFs of the Al_3O_{14} clusters were obtained using the published atomic coordinates of jadeite[36], chantalite[37] and $Al_2(OH)_2TeO_3SO_4$[38].

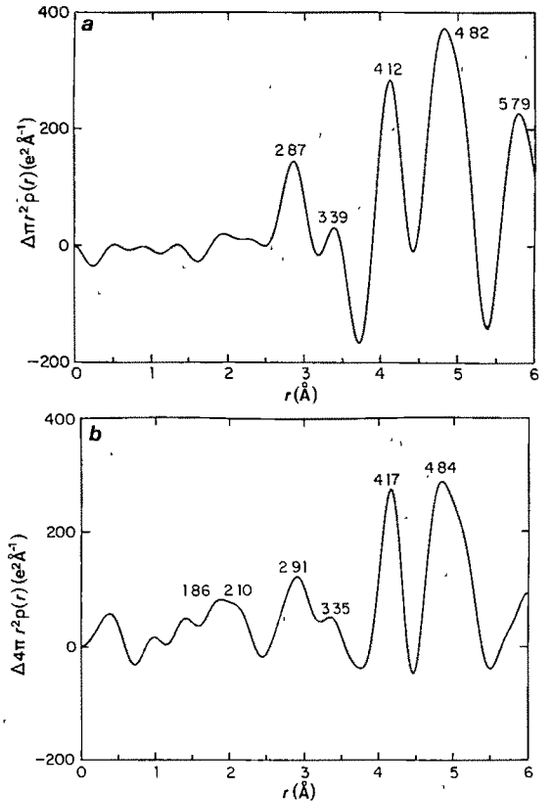

Fig. 2 RDFs for non-framework Al species in HY-DHV (*a*) and HY-DHSt (*b*)

Figure 1a shows a plot of $4\pi r^2\rho(r)$ against r for H-Y prepared at 300 °C in vacuum. The peaks were identified by comparison with calculated distances from the structure refinement of $H_{53\,8}Na_{2\,2}$-Y by Gallezot and Imelik[39]. The T-O value of 1.653 Å agrees well with the mean T-O distance of 1.648 Å calculated for $T = Al_{0\,29}Si_{0\,71}$ from ionic radii[40].

The RDF of HY-DHV (Fig. 1*b*) shows significant changes in peak position and poorer resolution of the T-T and O-O peaks at 3.13 and 2.69 Å and 4.39 and 3.86 Å, respectively.

More useful information is obtained, however, from subtraction of the HY RDF from the HY-DHV RDF Figure 2*a* shows that this difference spectrum is characterized by peaks at 2.87, 3.39, 4.12, 4.82 and 5.79 Å Because NMR studies of Freude *et al.*[19,20] show that extensive framework de-alumination occurs on dehydroxylation of H-Y at 650 °C in vacuum, we attribute the difference spectrum to the non-framework aluminium species.

To confirm that the difference spectrum of Fig. 2*a* is not an artefact, a further difference spectrum was obtained from the sample of Y dehydroxylated in steam at 890 °C (HY-DHSt) (Fig 2*b*) using the same H-Y as a reference[30]. The same prominent peaks as in Fig. 2*a* are present, but two additional peaks occur at 1.86 and 2.10 Å. It is apparent that a similar residual species is present in both HY-DHV and HY-DHSt.

The Al-O peak at 1.9 Å is only barely visible in HY-DHV. Although visible in HY-DHSt, its intensity is less than predicted from the calculated RDF. The increased intensity of the 1.9-Å peak and the generally narrower peaks for HY-DHSt probably reflect the increased degree of condensation and crystallinity of the NFA species in ultra-stable Y.

Table 1 summarizes the RDF peak positions from the NFA species in the two de-aluminated HY samples. The distances present in the NFA produced at 650 °C clearly correspond to a larger Al-OH cluster than the sample species listed earlier, that is, $Al(OH)^{2+}$, $Al(OH)_2^+$ or $[Al_2O]^{4+}$.

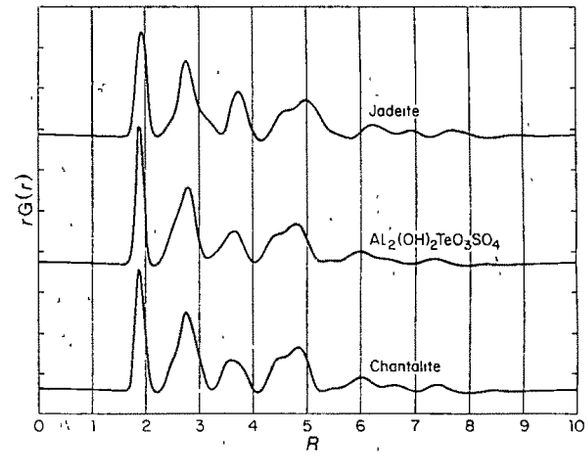

Fig. 3 Calculated RDFs for Al_3O_{14} clusters

To help identify the NFA species, we have calculated the RDFs of $Al_3(O,OH)_{14}$ groups extracted from the edge-shared octahedral chains in jadeite, chantalite and $Al_2(OH)_2TeO_3SO_4$. From the RDFs shown in Fig. 3, it can be seen that edge-shared octahedral clusters result in RDF peaks at positions similar to those shown in Table 1. The most prominent peaks occur at 1 9 Å (Al-O), 2.8 Å (O-O,Al-Al), 3.5 Å (Al-O), 3.8 Å (O-O), 4 4 Å (Al-O), 4.8 Å (O-O), 5.5 Å (O-O) and 5.9 Å (Al-O), where the values in parentheses indicate atom pair interactions calculated separately. This similarity suggests that the NFA species in HY-DHV and HY-DHSt contain edge-shared octahedral $Al_mO_n(OH)_p$ chains.

Two significant differences exist between the NFA peaks and those of the $Al_3(O,OH)_{14}$ clusters. First, the NFA peak at 1.9 Å is considerably broader and less intense than the 1.9-Å peak in the chains. The breadth could result from the considerable disorder caused by a large number of terminal OH groups expected in 10-Å clusters located in the supercages of Y zeolite. The peak at 1.86 Å probably corresponds to terminal OH groups whereas the peak at 2.1 Å would correspond to bridging OH or O atoms. Second, the NFA peak at 4.1 Å is shifted considerably from the typical value of 4 5 Å for the $Al_3(O,OH)_{14}$ clusters and its intensity is greatly increased. This suggests a different arrangement of the chains from the simple isolated species used for the calculations. Further calculations of RDF spectra for other $Al_mO_n(OH)_p(OH_2)_q$ clusters and the known crystalline forms of Al oxides and hydroxides are in progress with the hope that one of these will correspond to the difference RDFs of Fig. 2.

It should be emphasized that the NFA species formed in this study corresponds to an advanced stage of de-alumination under shallow-bed conditions. Dehydroxylation of H-Y occurs at 450 °C in shallow bed conditions and 300 °C in deep-bed conditions[19,20]. The de-alumination carried out in this study is in the region of substantial dehydroxylation and therefore de-alumination No attempt has yet been made to look at the de-alumination species obtained at lower temperatures The species formed at 300-550 °C may well be different and could correspond to some of the species proposed to form before condensation as emphasized by Freude *et al.*[19].

We thank P. D. Antonio and J. H. Konnert for making the program RADMOR available and K. H. Gardner for assistance in the RDF calculations.

Table 2 Peak positions in calculated partial RDFs for $Al_mO_n(OH)_p$

$Al_mO_n(OH)_p$	Compound	Al-O	O-O	Al-Al	Al-O	O-O	Al-O	O-O	O-O	Al-O	O-O
Al_3O_{14}	Jadeite	2.00	2 80	3 05	3 70	3 85	4 55	5 00			6.20
$Al_3O_{10}(OH)_4$	$Al_2(OH)_2TeO_3SO_4$	1.90	2.80	3 00	3 60	3.80	4 40	4.85		6.00	
$Al_3O_6(OH)_8$	Chantalite	1.90	2.80	3 00	3.55	3.80	4 45	4.85	5.50	6 00	6.10

Kilometre-scale sheath fold at Mattmark and implications for transport direction in the Alps

Robin Lacassin & Maurice Mattauer

Département des Sciences de la Terre, Université des Sciences et Techniques, Place E. Bataillon, 34060 Montpellier Cedex, France

Folds were the first tectonic features of rocks to be studied and as such are taken as a reference for the interpretation of other structures. Intuitively, fold axes were assumed to be subperpendicular to the direction of transport. Nevertheless, many studies of metamorphic belts showing intense ductile deformation describe folds with axes close to the transport direction. In particular, sheath folds[1-9], are highly curvilinear folds elongated parallel to the direction of transport. We discuss here a spectacular large sheath fold situated in a crustal shear zone in the Monte Rosa nappe, Swiss Alps. Our analysis implies that both the geometry and significance of folds in the internal Alps must be re-examined. We further demonstrate the existence of crustal ductile shear zones in an area of the Alps where previously emphasis was generally placed on fold nappes; the movements on these shear zones is often tens of kilometres.

The Monte Rosa nappe (Fig. 1), Swiss Alps, representing the northernmost internal crystalline massif, is a spectacular example of deep ductile deformation. It is made up of Hercynian basement rocks, mainly gneiss and schists, intruded by late Hercynian granites[10] and unconformably covered by Permo-Carboniferous volcaniclastic rocks and by a series of Mesozoic sediments[10-12]. All these were intensively reworked during the Alpine tectonometamorphism with the formation of gneisses, micaschists and mylonites, and are tectonically overlain by the Zermatt Saas-Fee ophiolite thrust sheet[13].

The polyphase Alpine metamorphism may be divided into two major events: as a high-pressure eoalpine metamorphism[14,15], (the climax of this metamorphism occurred around 110 Myr ago in eclogitic conditions (15 kbar), followed by a decrease of pressure to 7-8 kbar until 60 Myr)[16,17], and the Alpine (s.s.) metamorphism at around 38 Myr ago[17,18], in greenschist to amphibolite conditions.

In the Monte Rosa area, as in all the pennine Alps, the intensity of the Alpine deformation is evidenced by large recumbent nappes[19,20] and the presence of a prominent Alpine foliation and intense microfolding[10,21-23]. However, such studies can only analyse fold geometry and usually describe several phases of folding[24]. The direction of transport is generally assumed to be perpendicular to the fold axes and the vergence of 'tectonic phases' is deduced from the apparent vergence of folds.

Our recent work[25,26] has attempted to study the deformation mechanisms using tectonic and microtectonic analysis. We obtained the following results: firstly, The most significant microstructure is the prominent stretching lineation. This is clearly recognized by the elongation of deformable markers (such as pebbles), the stretching of porphyroclasts or rigid inclusions (feldspars in gneissic rocks, dolomitic layer in marbles) and also by mineral elongation (biotite, phengite, recrystallized quartz, feldspar or calcite, elongation of pressure

shadow crystallizations). These lineations represent finite extension. On average they trend N 110° E, plunging slightly to the west-north-west. Despite variations (from N 70° E to N 140° E) which may be related to heterogeneities of the deformation[27], they are regionally coherent. Secondly, the major deformation observed is generally intense and progressive, and shows evidence of non-coaxial deformation such as quartz petrofabrics[28], coherent displacement along shear zones[27], deformed porphyroclasts and pressure shadows[25], and shear band cleavages. Overall characteristics, the deformation resembles the result of simple shearing. As in shear zones the stretching lineation in the intensely deformed areas seems to lie close to the direction of shear.[29,30] On a regional scale, the lineations trace approximately straight paths. Two different units can be distinguished on the basis of the determined shear senses[25]. The first, the Monte Rosa nappe and its sedimentary cover, is characterized by shearing to the west-north-west associated with crustal ductile and major thrusting towards the west-north-west. The second unit, the Portjengrat unit, situated immediately south of the Mischabel backfold, shows east-south-eastward shears. We believe this deformation to be related to antithetic ductile thrusting[31]. Finally the observed progressive deformation mainly occurred during retrograde metamorphism at about 40 Myr. It may represent a late, although intense, phase of a complex deformation history and is probably related to major thrusting during and after continental collision.

In the vicinity of Mattmark in the Saas valley, a large-scale 'eye fold' has been recognized[32] and studied[25]. It is well exposed (Fig. 1), between 2,700 and 2,200 m, in a cliff oriented NNE–SSW and has been partly mapped[11,21]. It affects the sedimentary rocks of the Gornergrat zone with Upper Triassic marbles in the core of the fold, surrounded by Lower Triassic quartzites. This structure is in turn surrounded by schists and paragneisses (probably Permo-Carboniferous) and overlain by a slice of brown calcschists (*schistes lustrés* of supposed Jurassic age) and by the Zermatt Saas-Fee ophiolitic thrust sheet[13].

From the neighbouring summits (around 3,000 m) the 'eyed' structure is picked out by marble layers. On the outcrop both quartzite and marble layers surround the eye without discontinuity and define a closed structure (Fig. 1). The stretching lineation is generally prominent; in quartzites, very elongated

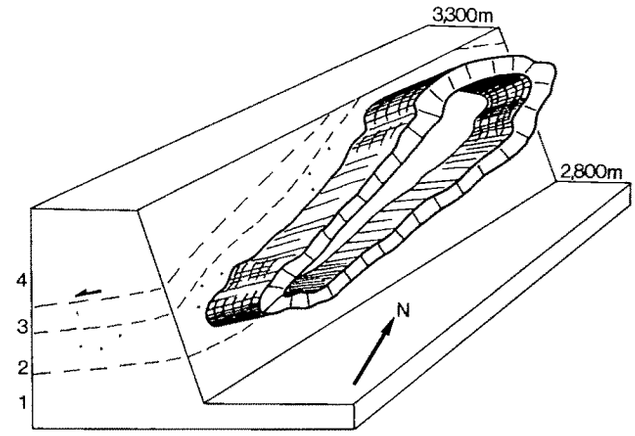

Fig. 3 Schematic structure of the 'eye fold' 1, Paragneiss and schists; 2, quartzites; 3, calcschists; 4, ophiolitic thrust sheet (mainly serpentinites)

pebbles, quartz rods and a mineral lineation (elongated phengite or quartz crystals) can be seen; in marbles or calcschists, the lineation is marked by boudinage of the dolomitic layers, the stretching of dolomitic inclusions or porphyroclasts (such as garnets) and elongation of minerals, and pressure shadows. These lineations show nearly constant direction in the studied area (Fig. 2) and on average trend N 120° E. Microfolds are isoclinal and more frequent in the north and south hinge zones of the eye fold (where we also observed small sheath folds and a mushroom-shaped fold) and also on the Jurassic calcschists. Both the fold axes (microfolds, north and south hinge zones of the eyed structure) and the intersection lineation, S_0/S_1 or S_0S_{1-2}, are parallel to the stretching lineation (Fig. 2).

The relative orientations of the bedding (S_0),and the fold axes suggest that the fold is cylindrical and that the eyed pattern is not a topographic effect (Fig. 3). Based on this structure and on the intensity, mechanism and kinematic of deformation, we interpret this eye fold to be a section lying subperpendicular to the axis of a large sheath fold[1,2]. This fold would be elongated parallel to the stretching lineation trend and of the order of several kilometres in size. It represents a synclinal structure with the younger rocks (marbles) in the core. There is no direct evidence for an east or west closure of this fold, that is, an eastward- or westward-facing nose. It is possible that a such large sheath fold is the result of a dramatic deformation associated with the westward crustal shearing rather than ductile backthrusting; if this is the case, the closure of the synclinal sheath fold should be to the east.

Other large folds exist in the Gornegrat zone. For instance, immediately north of the eye fold, we have described a refolded isoclinal fold of kilometre scale whose axis is always parallel to the stretching lineation[25]. On the metric scale, most folds show certain characteristics consistently over the whole area studied: they are highly isoclinal with very elongated limbs; the fold axes are generally straight and parallel to the stretching lineation; folds are clearly visible in sections perpendicular to the lineation where their apparent vergence is generally to the south-west. Nevertheless, folds showing opposite vergence (both to the south and north) on the same outcrop and mushrooom-shaped folds are relatively common. Two major folding phases (F_1 and F_2) with the same geometrical characteristics have previously been described[22].

Hence, the present deformation analysis indicates that folds in the Monte Rosa area (except obvious late folds) may represent either: (1) folds ("a folds")[33] with axes close to the long axis of the strain ellipsoid, as shown by the stretching lineation, which then approach the shear direction or (2) sheath folds; both result from or were strongly deformed during, the large progressive shearing.

The mechanism of formation of sheath folds during progressive deformation is well established[1,2]. They appear to be the

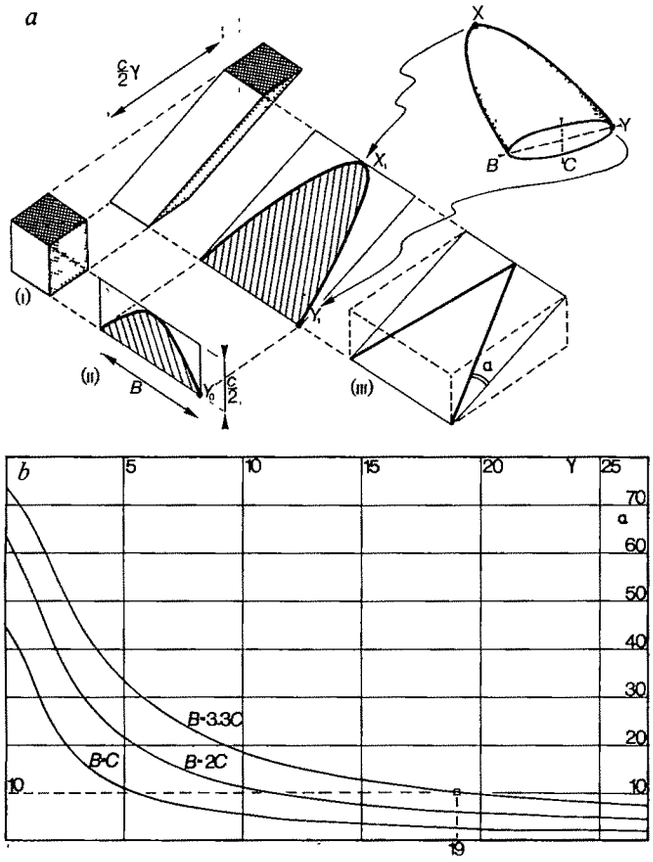

Fig. 4 Progressive reorientation of the limbs of a passive sheath fold. *a*, The model. (i) Idealized deformation of a cube of side. $C/2$ by simple shear (with shear strain γ); (ii) the same deformation applied to a cross-section of shape B, C representing the hinge zone of the fold; (iii) a simplification of this geometry to yield the angle α between the limbs and the long axis of the fold, as a function of γ and of the shape (B/C) of the fold. *b*, Curves of α versus γ. The curve $B=3.3C$ corresponds to the fold of Mattmark. γ is estimated to a minimum value of 19.

result of kinematic amplification of 'deflections' in the folded layers which produced curvilinear folds that became progressively more elongated during the deformation. The presence of a kilometre-scale sheath fold suggests that the shearing mechanism took place over a large area and caused very large deformation and transport. Commonly occurring folds lying parallel to the direction of shear were probably formed by reorientation, during the progressive deformation, of folds initially lying oblique to the shear direction[30,34]. Such oblique folds may have been induced during this deformation by the shearing of layers inclined relative to the shear plane[35,36].

In the absence of strain markers, an estimate of the shear strain can be obtained from a simple model of the geometry and evolution of the sheath fold. If exact, such an estimate would be more significant than a point-by-point strain analysis, because it would represent the average bulk shear strain for the whole volume of rock.

Assuming simple shear for the progressive deformation (Fig. 4*a*(i)), and a passive sheath fold, the shape of the hinge zone (Fig. 4*a*(ii)), represented in Fig. 4*a*(iii) by a triangle, is considered to be the result of kinematic amplification[2] of the deflection (Fig. 4*a*(ii)). We may calculate the angle α as a function of the shape of the sheath fold (B/C) and the shear strain (γ):

$$\alpha = \arctan\left(\frac{B}{C}\frac{1}{\sqrt{\gamma^2+1}}\right) \qquad (1)$$

Different curves, for different values of B/C, can now be plotted (Fig. 4*b*); the curve $B/C=10/3$ corresponds to the Mattmark fold We may then relate the characteristics of the observed sheath fold (the angle between the fold axes in the two hinge zones of the eye, which corresponds to 2α). Based on the approximately cylindrical shape of the Mattmark fold, we can consider the angle between the two axes to be $<20°$ (that is, $\alpha \leqslant 10°$). This leads to a minimum estimate for the bulk shear strain of $\gamma=19$, for a fold with the observed dimension $(B/C=10/3)$. Although this is an oversimplified model (which assumes simple shear, unknown shape of the deflection, and only passive reorientation), such an estimate may be a useful average value for the bulk shear strain. It agrees with the microstructural and textural characteristics of rocks such as: the elongation of quartz pebbles in conglomerates[25] (λ_1/λ_3 up to 50 and a K parameter close to 1 where λ_1 and λ_3 are finite strain axes and K is the shape parameter for the strain ellipsoid and is 1 when in plane strain); mylonitic microstructures[37]; and well-defined preferred lattice orientation of quartz.

In terms of transport, for a shear zone 1 km thick (minimum thickness for the intensely sheared area situated at the top of the Monte Rosa nappe), the value for γ obtained requires a minimum displacement of ~20 km. Note that much more movement may occur on discrete fault zones.

Such an analysis, associating folds with a deformation mechanism, has several implications.

First, for highly deformed areas, it seems logical to assume that folds perpendicular to transport ('b fold') cannot exist except in the case of late folds. This is true for mylonite zones[38] and also for deep parts of mountain belts such as the Himalayas[33], the Alps[39,40] or the North American Cordillera[41,42]. Hence, geometrical analyses of folds are not good kinematic indicators and must be used in association with analyses of ductile deformation mechanisms.

Second, this work demonstrates the importance of thrust displacements of several tens of kilometres along ductile shear zones, in an area where previously much emphasis was placed on fold nappes[19,22–24]. As has already been proposed for the French–Italian Alps[40], deformation analyses show that the evolution of the Swiss part of the belt is highly logical, and is dominated by thrusting towards the west-north-west, without major gaps between the external and internal Alps.

Finally, deformation analysis should be carried out on all the internal parts of the Alps. Some advances have been made on the French–Italian part[43,44], but in the famous Pennine nappes of the Swiss Alps[19,20] studies have concentrated on the superposed folding[23,24,45]. According to the highly deformed state of the rocks, fold geometry seems to be unrelated to the kinematic evolution, except in the case of late folds. It is probable that major deformations occurred in a shear context[46,47] with the formation of stretching lineations[48,49] tracing the shear directions. It would now be of great interest to study ductile deformation and its kinematics and to relate it to the fold geometries, with a view to analysing sheath folds[47] and folds subparallel to the shear directions.

An early Cambrian rift to post-rift transition in the Cordillera of western North America

Gerard C. Bond, Nicholas Christie-Blick, Michelle A. Kominz & William J. Devlin

Lamont-Doherty Geological Observatory of Columbia University, Palisades, New York 10964, USA

The upper Proterozoic and lower Palaeozoic wedge of miogeoclinal strata in the North American Cordillera is widely regarded as evidence for a proto-Pacific passive margin[1–3]. The rifting history of this margin appears to have been protracted, possibly spanning >200 Myr in a tectonic setting that is not well understood[3]. Quantitative subsidence analyses of lower Palaeozoic strata between British Columbia and Utah, however, provide indirect evidence that the transition from rifting to post-rift cooling occurred within a relatively short interval of time, although probably not synchronously, between 600 and 555 Myr (refs 4–6). This age is significantly younger than that implied in previous studies[1,2]. We describe here new field data, which, together with published geological data, provide direct evidence of a latest Proterozoic or early Cambrian age for the rift to post-rift transition. The data support recent arguments for widespread initiation of passive margins around the edge of the North American craton close to the Cambrian–Precambrian boundary[7].

Indirect evidence for the ages of the rift to post-rift transition as well as for the final rifting phase were inferred from tectonic subsidence curves for early Palaeozoic strata in the Cordilleran miogeocline[4–6] (Figs 1, 2). The strata (ranging from early Cambrian to late Ordovician in age) are laterally continuous, stable-shelf deposits and are regarded as part of an extensive post-rift continental terrace[1–3]. The tectonic subsidence curves have the same form as the age–depth curve for ocean floor (Fig. 2). This indicates that, as in modern passive margins, the post-rift tectonic subsidence was controlled mainly by contraction of the lithosphere resulting from the decay of thermal anomalies generated during rifting[4–6]. We emphasize, however, that the curves do not distinguish between margins adjacent to an open ocean or a back arc basin. The steep slopes of the curves, which are a function of the rates of heat loss, place the maximum age for the beginning of post-rift cooling at ~600 Myr (refs 4–6). This is because older ages for initiation of post-rift cooling, at 650 Myr, for example, would require anomalously high rates of heat loss from the Cambrian ocean floor, reaching at least 160%

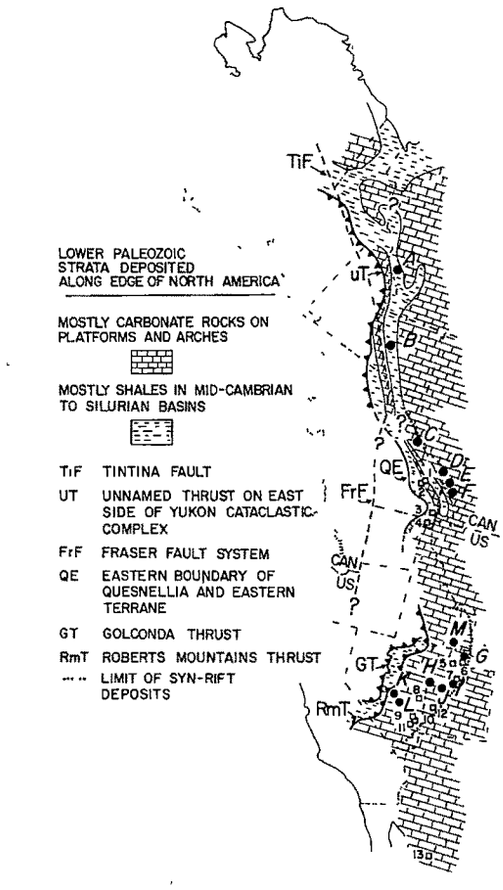

Fig. 1 Distribution of the lower Palaeozoic miogeoclinal facies in western North America (modified from ref. 5). UT, QE, GT and RMT are major structural boundaries of various terranes accreted to western North Amerca in post-early Palaeozoic time[3]. These boundaries mark the westernmost preserved edge of the lower Palaeozoic North American continent. Ti–FrF is a major right-lateral transcurrent fault system[3]. The dotted outline of western North America gives the position of this region after restoration of the right-lateral transcurrent movement on the Tintina–Fraser fault system[5]. Heavy dotted lines indicate the approximate eastern limits of the latest Proterozoic or earliest Cambrian post-Windermere rift deposits in the southern Canadian Rockies and in Utah–Nevada. ●, Locations of sections in which tectonic subsidence has been calculated[4,5]. □, Locations where mafic extrusive rocks occur in post-Windermere rift deposits that record the final (latest Proterozoic or early Cambrian) rifting in the margin. Sources: 1,2,3, Hamill Group[15,16,35]; 4, Three Sisters Formation (although the volcanics may be in the Windermere Supergroup, F. Miller, personal communication); 5, Mutual Formation (Crittenden, unpublished mapping); 6, Browns Hole Formation[23]; 7, Tintic Quartzite[30]; 8, 12, Prospect Mt Quartzite[26,29]; 9–11 Stirling Quartzite[26]; 13, Sonora[33,34].

of that of the modern ocean floor[5]. The high rates of post-rift cooling further indicate that relatively little heat was lost during rifting, and in terms of finite rifting models[9], the duration of the final rifting phase probably did not exceed 10–20 Myr. The age of final rifting, therefore, could not be much older than our inferred maximum estimate for the rift to post-rift transition.

The subsidence data do not preclude earlier extensional and heating events, which are indicated by geological evidence and have profoundly influenced the structural evolution of the margin, probably since the Middle Proterozoic[2,3,10]. However, igneous rocks thought to be associated with late Proterozoic rifting in the margin have radiometric ages of ~900–750 Myr (refs 8, 10, 11), and clearly are too old for the final rifting of the margin. Our mapping in the southern Canadian Rockies and in Utah, together with a synthesis of published data, have led to the identification of a widespread younger rifting event

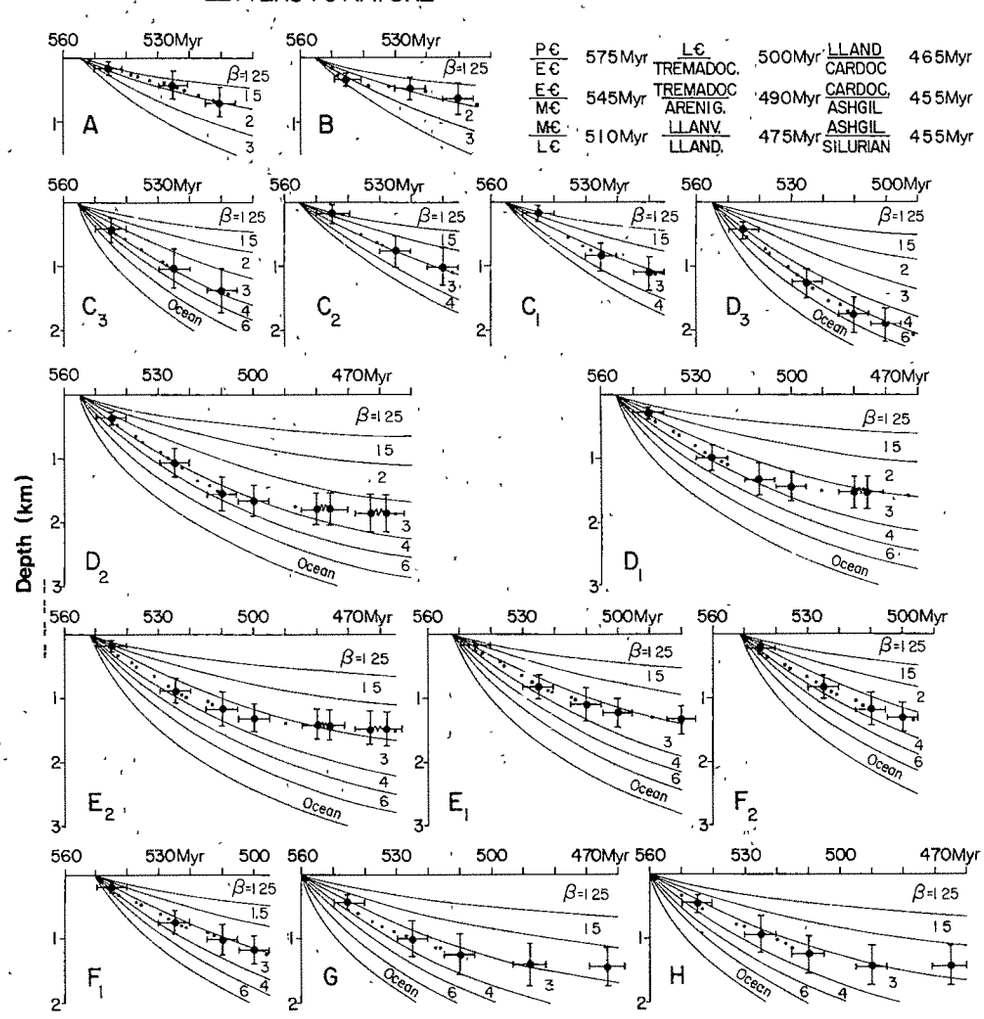

Fig. 2 Tectonic subsidence (●) for sections located in Fig. 1 compared with thermal subsidence curves from the McKenzie stretching model[36] (solid curves). Large dots are stratigraphical boundaries to which numerical ages have been assigned. Small dots are formation boundaries positioned by assuming constant sedimentation rates between dated boundaries. Vertical bars give the range between maximum and minimum values of tectonic subsidence[4]. Horizontal bars give an assumed ±5-Myr error for stratigraphical correlations with numerical ages β, Crustal stretching factors from the McKenzie stretching model; β values corresponding to the subsidence curves are not necessarily the stretching factors for the passive margin. Letters with subscripts designate different sections lying along east–west lines at locations that are too close to indicate separately in Fig. 1. The higher subscript numbers designate the more westerly sections. Most of the sections with subscripts are >15 km apart on a non-restored base Numerical ages assigned to the stratigraphical boundaries[20] are shown in the upper right-hand corner. Stratigraphical boundaries are from ref. 37.

whose age appears to be compatible with the high rates of post-rift cooling in the margin.

In the southern Canadian Rockies, limited evidence for younger rifting has been reported from the Hamill Group west of Golden[4,12] and from the McNaughton Formation near Jasper[13] (Fig. 3). Both deposits underlie strata with early Cambrian trilobites and overlie the Windermere Supergroup (Fig. 4*a*), a widespread stratigraphical unit that was deposited during rifting in late Proterozoic time (refs 2, 3, 10, 11). Both the Hamill Group and McNaughton Formation contain distinctive thick sequences of feldspathic sandstones and conglomerates[13–16] (Fig. 4*a*). In the Hamill Group west of Golden (Fig. 3), shallow-marine sediments pass abruptly into deeper marine deposits that contain resedimented sandstones, pillowed lavas and mafic volcaniclastic debris[12,15,16]. These facies changes are regarded as evidence of syn-depositional faulting accompanied by extrusion of mafic rocks[12]. Similarly, near Jasper, abrupt changes in thickness in the McNaughton Formation have been interpreted as evidence of syn-depositional faulting[13]. Strata of the Hamill Group and the McNaughton Formation pass gradationally upwards into the lower Cambrian mature quartz sandstones with *Skolithos* that are part of the early post-rift strata of the margin (Fig. 4*a*). Neither, however, is overlain by post-rift strata that are suitable for quantitative analysis, and their precise stratigraphical postion relative to a rift to post-rift transition cannot be inferred from subsidence data.

Recent field work in areas east and south of the exposures of the McNaughton Formation and Hamill Group (between 51°45′ and 52°30′, Fig. 1) has indicated that at least two of the sections analysed, SF and MtWi, and probably HL7b and GL as well (Fig. 3), are underlain conformably by a rift-like deposit that is at least 500 m thick. This deposit forms a distinctive basal unit of the Gog Group and is broadly correlative with the McNaughton Formation and at least the lower part of the Hamill Group[17] (Fig. 4*a*). The exact stratigraphical relation of this deposit to formally recognized strata in the region is not yet established, however, and we refer to it informally as a basal conglomeratic unit of the Gog Group.

A rift origin of the basal conglomeratic unit is suggested by a striking succession of cross-bedded, poorly sorted arkosic to subarkosic sandstones and conglomerates interbedded with thin layers of red shales and siltstones in the lower two-thirds of the unit (Fig. 4*a*). The sandstones and conglomerates contain ~30–80% quartz, 15–50% feldspar, more than half of which is a distinctive pink alkali feldspar as much as 2 cm across, and 5–20% rock fragments consisting mainly of quartzite, chert and granitic clasts. A total of 219 measured orientations of trough axes and large-amplitude (50 cm to 2 m) cross-beds, corrected for tilting, indicate mainly unimodal westerly current flow. The coarse grain size, arkosic composition, abundance of red shales together with westerly palaeocurrent directions suggest a fluvial or alluvial fan environment and a strongly uplifted source in crystalline basement to the east. An easterly provenance in crystalline basement has also been suggested for the McNaughton Formation based on palaeocurrent measurements and sandstone compositions[13,18]. The abrupt terminaton of the conglomeratic unit between Mt Chephren and Bow Pass (Figs 3, 4*a*) could reflect deposition against a fault scarp or hinge zone flanking the easterly basement source. The conglomeratic unit of the Gog Group grades upward into mature quartz sandstones with *Skolithos*, which are correlative with the post-rift deposits in the upper part of the McNaughton Formation and in or above the upper part of the Hamill Group (Fig. 4*a*) These *Skolithos*-bearing strata form the base of the sections used in subsidence analyses.

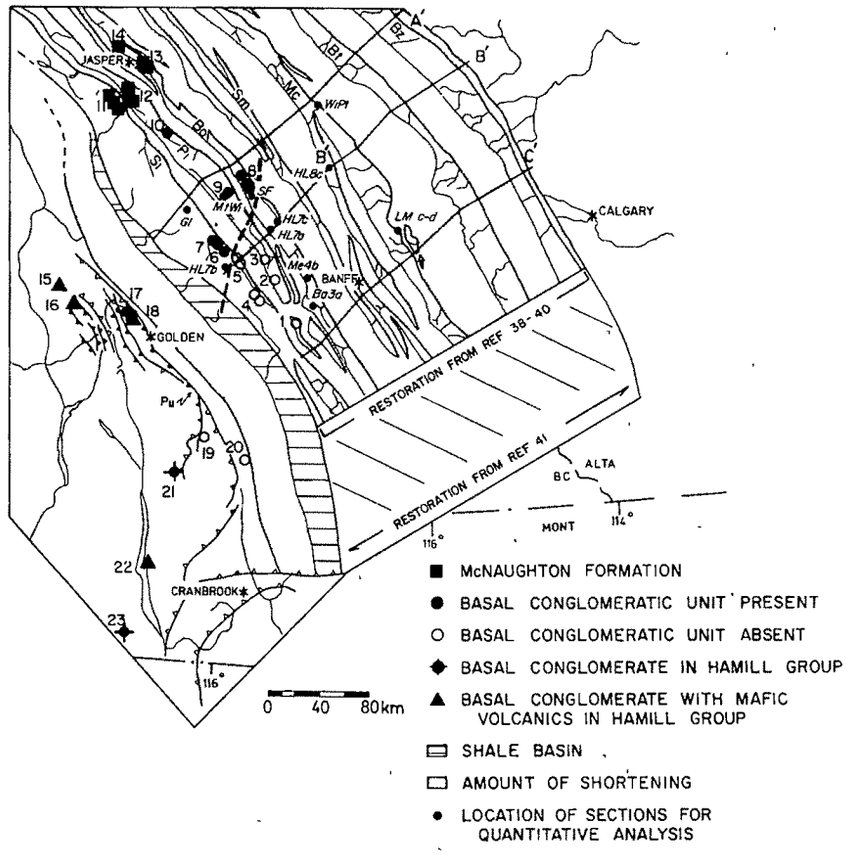

Fig. 3 Distribution, on a palinspastic restoration, of the uppermost Proterozoic to lowest Cambrian strata that are interpreted to record the final rifting and the transition to post-rift subsidence in the southern Canadian Rockies. Large filled circles, solid circles, solid circles with cross, solid squares, open circles and solid triangles mark localities examined in the field Open circles west of Banff are the Gog Group and south of Golden are the Cranbrook Formation. Stippled area is the amount of shortening between thrust panels that are unpatterned The shortening in the shale basin has not been determined from balanced sections and is assumed here to be equal to the amount of shortening in the carbonate bank (a factor of 2). The displacement on thrusts west of the shale basin has not been estimated. Italic letters correspond to analysed sections shown in Fig. 1. *WiPt*, *SF*, *MtWi*, *GL* are at locality D, Fig. 1; *HL8c*, *HL7c*, *HL7a*, *HL7b* are at locality E, Fig 1, and *LMC-D*, *Me4b* and *Ba3a* are at locality F, Fig. 1. Lines A′, B′ and C′ are lines of palinspastic restoration which are control for restored positions of thust plates[38-42]. The dashed line is the approximate position of the southeastern edge of the basal conglomeratic unit.

In the McNaughton Formation, the change from coarse feldspathic sediments to mature, marine quartz sandstones, which we assume is approximately correlative with the end of final rifting and the transition to post-rift subsidence, occurs in the lower part or below the early Cambrian *Fallotaspis* trilobite zone[19] (Fig. 4*a*). The transition to post-rift subsidence, therefore, lies near the base of the Atabanian Stage or in the Tommotian Stage. These stages are not well dated but are thought to range from slightly younger than 570 Myr to ~590 Myr (ref. 20). If the correlation of the McNaughton Formation with the basal conglomeratic unit and the Hamill Group suggested in Fig. 4*a* is even approximately correct, there is excellent agreement between the stratigraphical position of the rift to post-rift transition and the age of that transition inferred from the subsidence data.

There is also evidence, from work in progress, for syn-depositional rifting in the western United States, in uppermost Proterozoic and lower Cambrian rocks that are broadly correlative with the succession in the southern Canadian Rocky Mountains (Figs 1, 4*b*). The principal evidence for rifting is the occurrence of feldspathic sandstones and conglomerates, relatively abrupt lateral facies and thickness changes, regionally variable palaeocurrent directions and the presence of mafic volcanic flows and volcaniclastic conglomerates. Few chemical data are available for the volcanic rocks, but the rocks appear to be of tholeiitic to alkalic affinities, consistent with continental rifting[1,21]. The feldspathic sandstones and conglomerates occur sporadically, but in places constitute units several hundred metres thick[22,23]. Sequential changes in mineralogical maturity and grain size are locally abrupt, consistent with episodic uplift and exposure of crystalline basement. In Utah, for example, medium- to fine-grained, well-sorted, shallow-marine (?) quartzite of the upper Browns Hole Formation is overlain with sharp contact by arkosic, poorly sorted fluvial (?) conglomerate of the Geertsen Canyon Quartzite[23] (Fig. 4*b*). In general, the occurrence of lateral facies and thickness changes tends to be obscured by formational nomenclature which emphasizes the regional persistence of gross stratigraphical units. However, in one well-documented example, the middle member of the Wood Canyon Formation in southeastern California[22], strata thicken and coarsen to the north-east and contain south-west-directed palaeocurrents, whereas associated stratigraphical units thicken to the west or north-west, and yield west- to north-directed and polymodal palaeocurrents[24,25].

The inferred rift deposits in Utah and Nevada overlie strata that are thought to be correlative with the Windermere Supergroup in the Canadian Cordillera[26,27], and they pass upward into lower Cambrian mature quartz sandstones with *Skolithos* that lie at the base of the post-rift strata from which the subsidence data were collected (Figs 1, 2, 4*b*). In the Delamar area of eastern Nevada, lithostratigraphical correlation with a section in the White-Inyo Mountains, California, suggests that the transition upward into post-rift mature quartz sandstones occurs near the base of or below the *Fallotaspis* trilobite zone[26,28]. In the Wah Wah[29] and East Tintic[30] sections, the transition to post-rift strata is not well dated but seems to occur at about the same stratigraphical level relative to the base of the middle Cambrian as in the Delamar area[26]. In the Huntsville section[23,27], the transition may be slightly lower stratigraphically but is probably broadly correlative with that to the south. In the western United States, therefore, as in the southern Canadian Rockies, the stratigraphical position of the final rifting to post-rift transition is in good agreement with the age of that transition inferred from the subsidence data.

The age of the final rifting episode can also be estimated from stratigraphical relations at several localities in the miogeocline. Near Jasper, in the southern Canadian Rockies, the uppermost 500 m of the underlying Windermere Supergroup (Miette Group, Fig. 4*a*) contains the trace fossils *Platysolenites* and *Didmaualichnus* and a microbiota with *Campitius* and *Volborthella* spp.[13,31]. These are reported to occur in the Tommotion Stage (~570–590 Myr) and possibly younger stages of the early Cambrian[13,32], but their range is not well established. The rift deposit clearly lies above the Windermere Supergroup and only a short distance beneath probable earliest Cambrian strata, suggesting a latest Proterozoic age for the deposit. Simlarly, in Utah and Nevada, the mafic volcanic rocks and feldspathic deposits occur a short distance below the *Fallotaspis* zone in

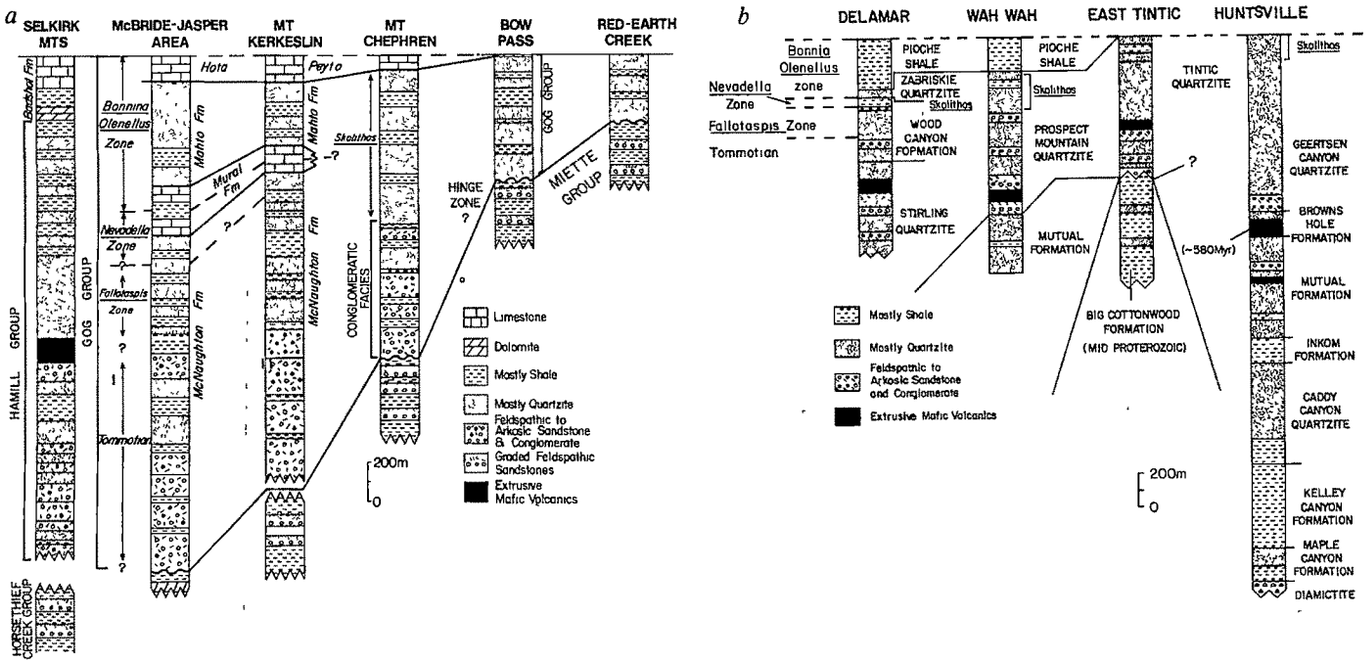

Fig. 4 *a*, Respresentative sections of the basal conglomeratic unit of the Gog Group and its probable equivalents in the McNaughton Formation and the Hamill Group. Columns show the transition of these strata to post-rift deposits of the miogeocline. These strata are interpreted as evidence of post-Windermere rifting and latest Proterozoic to earliest Cambrian transition to the post-rift phase in the margin. The Horsethief Creek Group and the Miette Group compose the Windermere Supergroup west and east of the Rocky Mountain Trench, respectively. Dash-dot lines are approximate boundaries between trilobite zones. The base of the middle Cambrian (uppermost dash-dot line) is the reference datum of the sections. The sections are located in Fig. 3 as follows: 1, Red Earth Creek; 5, Bow Pass; 7, Mt Chephren; 12, Mt Kerkeslin; 14, McBride-Jasper area; 17, 18, Selkirk Mts. Sources: Red Earth Creek, Bow Pass and Mt Chephren from G.C.B., Ma and M.A.K. (field work 1982 and 1983); Mt Kerkeslin from refs 13, 43; Selkirk Mts from ref. 16. Faunal zones are from ref. 19. *b*, Representative sections from Utah and Nevada indicating inferred final rift deposits and the transition to post-rift strata for comparison with similar successions in the southern Canadian Rockies. Dash-dot lines are approximate boundaries between trilobite zones. The ages in the Delamar section are based on lithostratigraphical correlation with biostratigraphically dated strata in the White–Inyo Mountains of California, about 300 km to the west. The upper part of the Stirling Quartzite is correlated with strata assigned a Tommotian age in California; the base of the Tommotian stage has not been established in the western United States[34]. Sections located in Fig. 1 and sources as follows: 11, Delamar[26]; 12, Wah Wah[29]; 7, East Tintic[30]; 6, Huntsville[23,27].

strata that are probably Tommotian in age (Fig. 4*b*), which, together with the 580-Myr Ar/Ar age from the volcanic rocks in northern Utah[21], suggests that rifting occurred in the latest Proterozoic and/or earliest Cambrian. Finally, in Mexico, post-rift carbonate rocks and quartz sandstones of early Cambrian age pass gradationally downward into nearly 300 m of strata containing mafic lava and mafic volcaniclastic rocks. These volcanic deposits seem to be correlative with, or slightly older than, the lower part of the *Fallotaspis* zone[33,34]

Large parts of the Cordilleran miogeocline from Canada to Mexico, therefore, contain evidence of late Proterozoic rifting events that led to the formation of an extensive proto-Pacific passive margin. These events began perhaps as early as 800–900 Myr but appear to have terminated in a final, distinct and short-lived phase near the Cambrian–Precambrian boundary. The age is compatible with ages for the final rifting and rift to post-rift transition inferred from quantitative subsidence data. The results of the subsidence analyses were fundamental to this research, not only focusing on the problem of the ages for rifting, but also in predicting the stratigraphical position where the final rift deposit and the transition to post-rift strata should occur. This greatly facilitated the search for these deposits in the field. We have now identified these deposits in a large region in the southern Canadian Rockies and in an even larger area between southeastern Idaho and southeastern California (indicated by the dotted lines in Fig. 1). It seems that final rifting along a large portion of the proto-Pacific margin of western North America occurred at about the same time as rifting in the early Palaeozoic miogeocline in Arctic Canada and along an extensive portion of the Iapetus margin in the US Appalachians and Newfoundland[7]. The contemporaneity of these events support recent arguments for rifting around nearly all of the perimeter of North America close to the Cambrian–Precambrian boundary[7].

The research was supported by NSF grants EAR 82-12737 to G.C.B. and H. Brueckner and EAR 83-13230 to G.C.B. and by the Donors of the Petroleum Research Fund, administered by the American Chemical Society (PRF 16042-G2 to N.C.-B.). Direct measurements of secondary currents in a meandering sand-bed river

C. R. Thorne*, L. W. Zevenbergen*, J. C. Pitlick†, S. Rais†, J. B. Bradley† & P. Y. Julien†

* Department of Geography and Earth Science, Queen Mary College, University of London, Mile End Road, London E1 4NS, UK

Natural channels often adopt a meandering course. Water flow in meander bends is three-dimensional, consisting of primary velocities which are tangential to the bend, and secondary velocities, which are in the radial plane. The pattern of secondary flow strongly affects the distribution of primary velocities. This in turn affects the distribution of erosion and deposition in the bend and the way in which the channel shifts and changes shape. Measurements of primary and secondary flows in a meandering gravel-bed river[1,2] show that, in addition to the widely recognized main secondary circulation driving surface water outwards and bed water inwards, there can be a small cell of reverse rotation at the outer bank. Further data have been collected in a sand-bedded river at low, intermediate and high discharges. The results confirm the existence of the main and outer bank cells but also indicate that in some bends the main cell does not extend to the inner bank. In fact, secondary flow at the inner bank of wide, shallow bends is directed radially outwards over the whole flow depth at all in-channel flows. This indicates that some models of bend flow and channel development may be significantly in error.

Secondary currents are defined as currents that occur in a plane normal to the axis of primary flow[3]. In meander bends, they develop by skewing of cross-stream vorticity into a long-stream direction[3,4]. The resulting skew-induced secondary circulation carries fast surface water towards the outer bank and slower bed water towards the inner bank.

At the outer bank, the primary flow, secondary circulation, and bank interact to produce a small cell of reverse rotation to the skew-induced cell. This cell occupies the channel to a distance one or two times the bank height away from the bank. Although this is a small proportion of the cross-section in most rivers, the outer bank cell is still important because it strongly affects the distribution of boundary shear stress, thereby influencing bank erosion processes[5,6].

In the central part of the channel, helical skew-induced flow produces inward velocities near the bed, which sweep bedload towards the inner bank. Sediment accumulation as a point bar at the inner bank gives the channel an asymmetrical cross-section. The balance between the transverse, upslope component of fluid drag on a bedload particle, and the transverse, downslope component of particle weight has been used as the basis for models of bed topography in bends[7,8]. This view of secondary flow-point bar interaction has been challenged recently[9]. Dietrich and Smith suggest that secondary flow above the point bar is directed radially outwards over the whole flow depth and that the helical skew-induced cell is confined to the deepest, or thalweg, portion of the cross-section Sediment accumulation is

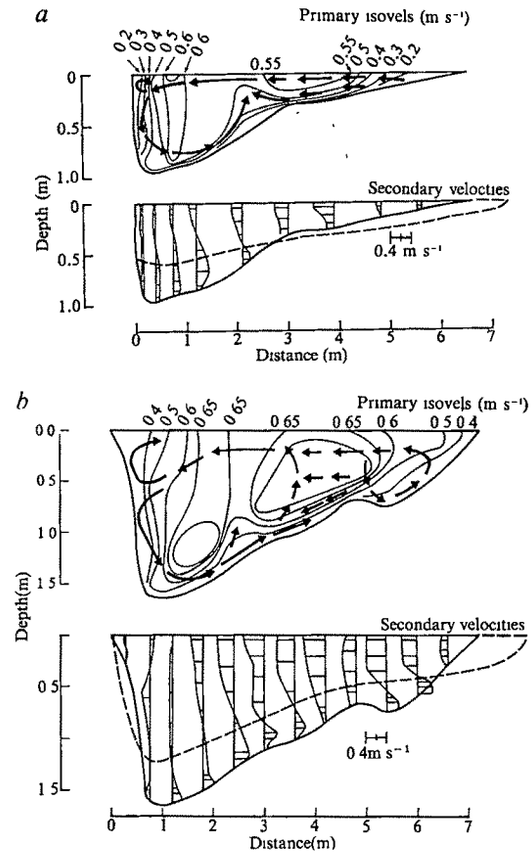

Fig. 1 Upstream bend apex, discharge: *a*, 1.7 $m^3 s^{-1}$; *b*, 4.0 $m^3 s^{-1}$. Dashed channel section represents that at the previous measurement section, ~6 m upstream.

then concentrated on a steep transverse slope called the point bar face, between the upper point bar (point bar platform) and the thalweg, where near bed flow converges and there is strong upwelling. Bridge[10] suggests that this pattern of flow and point bar building is a characteristic of point bar emergence at flows below about two-thirds bankfull. He suggests that at such low stages the point bar topography causes flow convergence at the bend entrance, but that such patterns are replaced by helical flow at formative (that is, bankfull) discharge.

To help to resolve this discussion, data were collected in this study over a range of discharges in meander bends of the Fall River in Rocky Mountain National Park, Colorado. The reach studied has a bankfull capacity of about 4 $m^3 s^{-1}$ and well developed meanders with a sinuosity of 2.2. The annual hydrograph is dominated by snowmelt runoff, resulting in long periods of almost steady bankfull flow in May, June and July. The gradient is ~0.1%. The bed material is sand, $D_{50} = 1.0$ mm, moving in dunes, ripples and as suspended load. Sediment availability has been greatly increased by erosion associated with the failure of Lawn Lake Dam on the Roaring River (an upstream tributary) on 15 July 1982. As a result, the bed is mobile at all discharges and point bars in the bends respond quickly to changes in flow stage.

Measurements were made at low, intermediate and bankfull stages, corresponding to discharges of 1.7, 2.8, and 4.0 $m^3 s^{-1}$. Long and cross-stream velocities were measured using an electromagnetic current meter capable of measuring two mutually perpendicular velocity components with an accuracy of ± 3 mm s^{-1}. All measurements were made from temporary bridges aligned at right angles to the outer bank, and care was taken to work only over dune crests, avoiding separation zones on the lee side of dunes. Data were collected at 18 sections evenly spaced along the channel through two consecutive bends. The complete data set is available[11,12] but because of limitations of space, only data for the intermediate and high flow at the

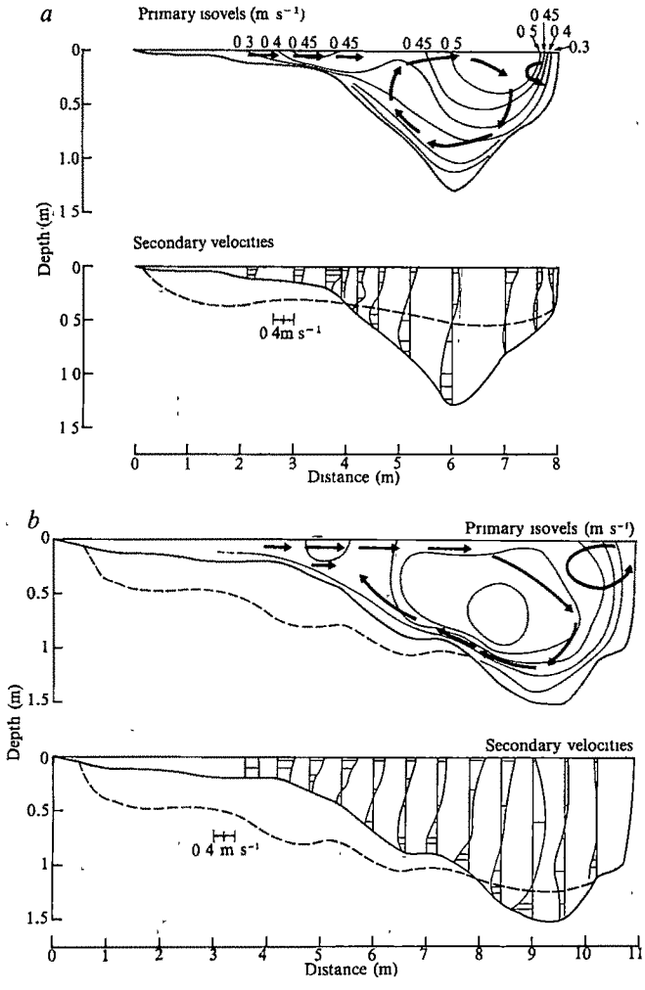

Fig. 2 Downstream bend apex, discharge: *a*, 1.7 $m^3 s^{-1}$; *b*, 4.0 $m^3 s^{-1}$. Dashed channel section represents that at the previous measurement section, ~4 m upstream.

bend apices are reported here. However, these sections do typify the different patterns found in the two bends. The long and cross-stream velocities were resolved into primary and secondary components using the method based on three-dimensional continuity recommended by Dietrich and Smith[9]. The results are shown in Figs 1, 2.

At both sections and flows the salient feature of the secondary circulation is the helical, skew-induced cell. However, close to the outer bank, a small cell of reverse rotation is clearly present, especially at bankfull flow. These cells are associated with distortion of the primary isovels and depression of the maximum primary velocity below the free surface in the outer bank region. The outer bank cell occupies the channel to a distance 1–2 times the bank height away from the outer bank, as observed elsewhere[5,9,10] and predicted theoretically[13].

The pattern of primary and secondary flows in the outer half of the channel changes little with stage at a bend, and is similar at both apices. This robustness is not present in the flow pattern in the inner half of the channel, where the two bends react differently to changing stage.

At intermediate flow, secondary flow over the point bar is directed radially outwards over the whole depth, as predicted and observed by Dietrich and Smith and by Bridge[9,10]. The reason for this is the dominance of the centrifugal force acting outwards over the hydrostatic pressure gradient, acting inwards. Also, the flow is shelving and narrowing in the longstream direction at the inner bank, as indicated in Figs 1*a* and 2*a* by the dashed lines showing the cross-section just upstream from the bend apex. Consequently, water is driven radially outwards to maintain continuity, leading to outward secondary flow. These arguments agree with the explanation put forward by the previous researchers[9,10].

At bankfull stage, the two bends show different flow patterns in the inner half of the channel. At the upstream bend, outward flow has been replaced by helical flow over most of the width, as predicted by Bridge[10]. The point bar has been scoured and reprofiled by the high flow and this, combined with the increased stage at almost constant width, has significantly increased the importance of the cross stream hydrostatic pressure gradient, which is now able to drive bed flow inwards. This is not the case at the downstream bend. Here, outward flow over the point bar persists up to bankfull discharge. The reason for this is that the width increases markedly with stage at the downstream bend, so that both the depth and the hydrostatic pressure gradient over the point bar remain small (Fig. 2*b*). Also, the point bar is more prominent in the downstream bend, so that shelving in the downstream direction is maintained at bankfull flow (Fig. 2*b*). This is not the case at the upstream bend, where high flow scouring produces deepening downstream at the inner bank (Fig. 1*b*).

We conclude that both patterns of flow in the inner half of the channel are possible and do occur in nature, depending on the morphology of the channel cross-section. Of particular importance is the stage–width relationship. Where there is marked widening with stage, outward flow persists to bankfull flow, but where width is almost constant with stage, helical flow expands almost to the inner bank. A quick survey of the Fall River bends revealed about equal numbers of bends falling into each category. As all the bends have the same bankfull discharge, sediment load, and bed and bank materials, there seems to be no obvious reason for the different morphologies, raising the possibility of there being two stable bend sections for a given set of independent controls. Clearly, point bar-flow interaction is a topic deserving further consideration and study.

This research was supported by the US National Parks Service, US Bureau of Reclamation, and Colorado State University.

Enhancement of marine primary production by nitrogen-enriched acid rain

Hans W. Paerl

Institute of Marine Sciences, University of North Carolina, Morehead City, North Carolina 28557, USA

The effect of acid rain on the *p*H of freshwater habitats is well known[1]. The acidity of rainwater is largely due to hydrated oxides of sulphur, nitrogen and carbon[2], which also constitute nutrients essential for plant growth. Most freshwater and marine environments contain sufficient quantities of inorganic carbon and sulphur to satisfy plant growth needs, but nitrogen inputs can at times fall short of growth demands[3,4]. Nitrogen limitation of phytoplankton growth is widespread and chronic in some marine waters[5–7]. I

report here that nitrogen-limited conditions in North Carolina near-surface waters are ameliorated following rainfall inputs; the most acidic rainfall events led to the greatest stimulation of phytoplankton growth. Continentally-derived acid rain consistently contained more inorganic nitrogen (NO_3^-, NO_2^- and NH_4^+) than near neutral rainfall generated from oceanic fronts. Marine primary production can thus be influenced by the source of rainfall in marginal environments.

Nutrient limitation and impacts of rainfall on phytoplankton growth were examined at three Atlantic Ocean locations on the east coast of North Carolina. Bogue Sound, a euhaline (30–34 parts per 10^3 (p.p.t)) sound separating the mainland from a barrier island (Bogue Island) served as an inshore location. Continental slope waters ~1 km offshore from Bogue Banks provided a near-shore habitat, while Gulf Stream waters 25 km offshore represented a more pelagic habitat All three locations commonly receive both acidic (continental origin) and near-neutral (oceanic origin) rainfall. Continental rain *p*H characteristically ranged from *p*H 3.5 to 5.5, while oceanic rain ranged from *p*H 5.5 to 6.8. Surface waters from these locations were collected in 20-l pre-cleaned polyethylene carboys throughout 1983–84, immediately brought to the Institute of Marine Sciences (IMS) and analysed for the soluble nutrients $NO_3^- + NO_2^-$, NH_3/NH_4^+, PO_4^{3-} and chlorophyll *a* content. Samples were collected during periods of minimal riverine runoff (salinities of at least 33 p.p.t.); however, Bogue Sound was occasionally sampled after freshwater runoff episodes, as experienced after the landfall of hurricane Dianna during mid-September 1984 (salinity = 27 p.p.t.).

Rainwater was routinely collected on the rooftop of IMS using pre-cleaned polyethylene buckets. Rainfall amounts and *p*H were recorded and nutrient chemistry was performed on rainwater used in bioassays.

Bioassays were performed in triplicate in 1-l pre-cleaned polyethylene Cubitainers, which were 85% transparent to photosynthetically active radiation (PAR = 400–700 nm). They were incubated in natural surface light and temperature conditions in a saltwater pond at IMS. Incubation periods lasted between 1 and 7 days. Freshly collected seawater was dispensed, followed by additions of either 10 or 20% v/v rainwater (RW) or distilled deionized water (DDW). Total bioassay volume was 900 cm^3. Parallel $N\text{-}NO_3^-$ (100 and 200 parts per 10^9 (p.p.b.), $P\text{-}PO_4^{3-}$ (50 and 100 p.p.b.), and combined NO_3^-/PO_4^{3-} additions were also made A 10-μCi aliquot of $^{14}C\text{-}NaHCO_3$ (68 μCi μmol ICN Corporation) was also added to each Cubitainer to monitor photosynthetic $^{14}CO_2$ assimilation as a growth-response parameter. All ^{14}C assimilation results were corrected for abiotic ^{14}C precipitation and liquid scintillation quenching. The fluorometric determination of chlorophyll *a* in 90% v/v $MgCO_3$-buffered acetone extracts served as an additional phytoplankton growth-response parameter.

Both oceanic and continental rain significantly ($P < 0.001$) stimulated phytoplankton primary production as observed by both $^{14}CO_2$ fixation and chlorophyll *a* production (Fig. 1). Stimulation was evident with both 10 and 20% v/v additions. The more acidic continental rainfall led to much higher magnitudes of stimulation (Fig. 1). Typically, 30–70% higher phytoplankton growth yields were observed in response to acidic as opposed to near-neutral rainfall additions. Parallel NO_3^- and PO_4^{3-} additions consistently revealed exclusive NO_3^- stimulation of phytoplankton production during 1983–84. Acidic rain also led to more sustained periods of stimulation. Generally, enhanced (over control) phytoplankton growth, as monitored by chlorophyll *a* production, continued for 6–7 days in response to acid rain additions (Fig. 2). Near-neutral rainfall led to initial growth stimulation, which decreased after 2–3 days (Fig. 2) Differential growth stimulation was not directly attributable to *p*H; neutralized (with NaOH) acid rain yielded results identical to untreated acid rain. Similarly, near-neutral rain made more acidic did not reveal greater stimulation. Furthermore, the addition of either acid or neutral rain failed to alter ($P < 0.001$) the pre-existing *p*H of seawater significantly (*p*H = 8.36). Accordingly, I attribute differential stimulation among, as well as between, treatments and controls to contrasting levels of dissolved inorganic nitrogen enrichment.

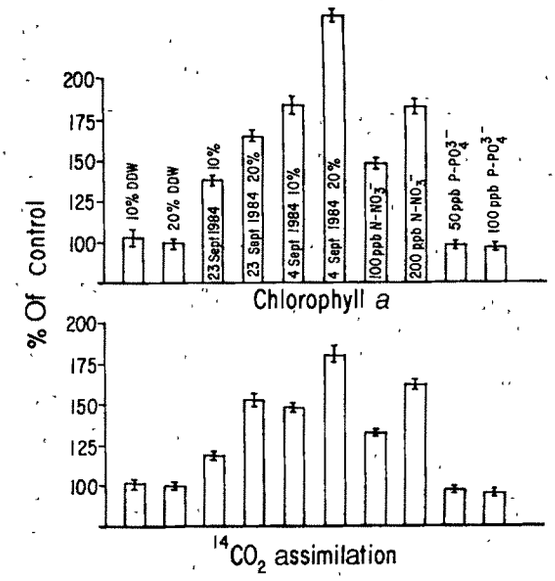

Fig. 1 Impacts of rainwater on Bogue Sound chlorophyll *a* production, and $^{14}CO_2$ assimilation following a 5-day *in situ* Cubitainer bioassay. All treatments were compared with controls (no additions). Both 10% and 20% v/v additions are shown. Rainwater collected on 4 September 1984 had a *p*H of 4.05, while 23 September 1984 rainwater had a *p*H of 5.85. Parallel 10% and 20% v/v distilled deionized water (DDW) additions revealed the impacts of equi-volume nutrient-free freshwater dilutions on Bogue Sound Water. Parallel $N\text{-}NO_3^-$ (100 and 200 p.p.b.) and $P\text{-}PO_4^{3-}$ (50 and 100 p p.b.) additions consistently showed exclusive stimulation of phytoplankton growth by nitrogen. Error bars indicate variability among triplicate samples for each treatment. Biostimulation by all rainwater and $N\text{-}NO_3^-$ additions was significant ($P < 0.001$) among the two growth parameters.

Chemical analyses of sea water from all sampling locations and bioassays demonstrated: (1) consistent NO_3^- depletion but PO_4^{3-} sufficiency during the main phytoplankton growth period (April–October); (2) rapid depletion of NO_3^- and NH_3/NH_4^+ enrichments supplied in rainwater, but a lack of concurrent PO_4^{3-} depletion either supplied in rainwater or as an individual nutrient, and (3) good agreement between the initial amount of NO_3^-, NH_3/NH_4^+ present in rainwater and the duration of phytoplankton growth stimulation. Lastly, a positive correlation existed between $NO_3^- + NO_2^-$ content and acidity of rainfall samples collected ($r^2 = 0.87$; $n = 15$).

Five additional bioassays, complementing those shown in Figs 1, 2, revealed that phytoplankton growth was nitrogen limited throughout the spring and summer of 1984. Atomic ratios of dissolved inorganic N : P ranged from 1 to 5 (weighted mean of 2.8), further evidence for consistent nitrogen-depleted conditions of these waters.

The choice of 10–20% (v/v) rainwater additions was based on the impacts of rainwater dilutions on near-surface (0–5 m depth) salinities following large (1–5 cm) rainfall events in coastal waters, before the dilution observed by enhanced terrigenous freshwater runoff. Near-surface salinities were commonly depressed by 2–3 p.p.t. immediately after such rainfall events. A 10% v/v bioassay rainwater addition depressed the salinity of coastal water by ~2.2 p.p.t. Hence, such additions provide reasonable approximations of natural rainwater dilution effects on near-surface seawater. Large storm systems are likely to mix rainfall inputs to depths >5 m; therefore, the estimates presented here apply to more localized short-lived storm activities, including the numerous summer thunderstorms and rapidly dissipating winter cold fronts often observed in this area.

Periodic offshore chlorophyll *a* samplings before and after storm events in 1984, substantiate bioassay-derived conclusions,

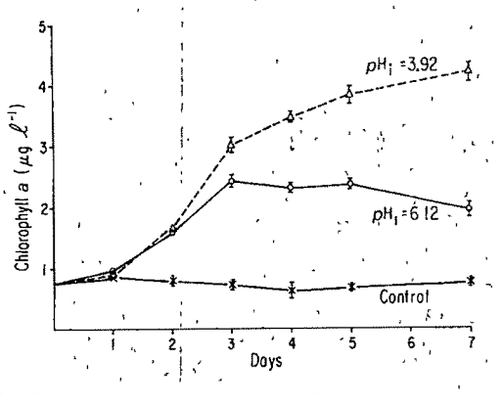

Fig. 2 Chlorophyll *a* production in Cubitainer bioassays subsampled daily following acidic versus near-neutral rainwater (10% v/v) additions. Acidic rainfall ($pH = 3.92$) characteristically showed higher magnitudes and longer-lasting stimulatory effects than near-neutral (pH 6.12) rainfall. Chemical analyses of acidic rainfall yielded the following results $N\text{-}NH_4^+ = 233$ p.p.b., $N\text{-}NO_3^- + NO_2^- = 459$ p.p.b., $P\text{-}PO_4^{3-} = 9.1$ p.p.b. Near-neutral rainfall: $N\text{-}NH_4^+ = 251$ p.p.b., $N\text{-}NO_3^- + NO_2^- = 219$ p.p.b., $P\text{-}PO_4^{3-} = 3.7$ p.p.b. Control was untreated Bogue Sound water incubated in parallel. Error bars show variability among triplicate samples. Beyond day 2, all treatments were significantly ($P < 0.001$) different from each other as well as from the control.

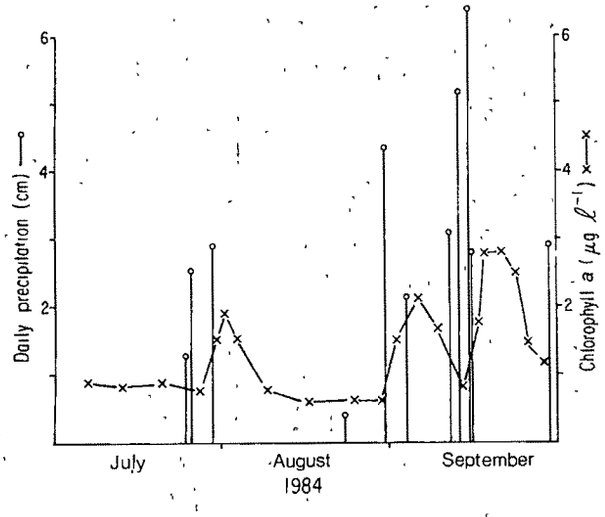

Fig. 3 Major (>0.1 cm per day) precipitation events recorded at Morehead City, North Carolina versus surface chlorophyll *a* concentrations sampled at an offshore loction 5 km south-east of Bogue Banks during July, August and September 1984. All chlorophyll *a* samples were from non-turbid waters free of runoff plumes and sediment resuspension. Extensive rainfall during mid-September was due to the passage of hurricane Dianna near the North Carolina coast.

namely, that precipitation nitrogen inputs lead to significant localized enhancement of phytoplankton production in these nitrogen-depleted waters. Characteristically, a 2-day lag occurs between extensive rainfall and enhancement of near-surface chlorophyll *a* levels (Fig. 3). Chlorophyll *a* enhancement can last from a few days to several weeks. The initial (within 3 days) enhancement closely follows direct precipitation inputs, leading to small but detectable increases in NO_3^- and NH_3/NH_4^+ concentrations. Freshwater runoff sources, as delineated by suspended fine-sediment plumes and the appearance of brackish water phytoplankton species and detritus, typically do not appear in these waters until 2–3 days after the onset of chlorophyll *a* enhancement. While direct precipitation inputs seem to be responsible for initial chlorophyll *a* enhancement, terrigenous runoff probably sustains such enhancement beyond a period of several days.

Experimental and observational findings indicate that localized inorganic nitrogen enrichment attributable to direct precipitation inputs can lead to enrichment of marine primary production in near-surface waters. Annually, chlorophyll *a* concentration ranges from >1 to 5 μg l^{-1} in these waters. The observed buildup of chlorophyll *a* concentrations following direct precipitation inputs (Fig. 3) therefore constitutes a substantial fraction of maximum levels. Acidic rainfall, being enriched in NO_3^- and NO_2^-, preceded the highest magnitudes of primary production stimulation. I therefore conclude that although pH impacts of acid rain are largely insignificant in well-buffered marine habitats, nutritive impacts are both detectable and may be of long-term consequence in shaping both patterns and magnitudes of phytoplankton production. Such potential impacts are expected to be of greatest importance in waters bordering the eastern margins of land masses supporting extensive industrial and urban development. These would include the eastern seaboards of the United States and the United Kingdom, the Baltic region and the Western Pacific waters bordering Japan, Korea and China.

This research was supported in part by North Carolina Sea Grant Project R/MER-1 and NSF grant BSR 8314702. I thank J. Kohlmeyer for collecting rainfall data during 1984, and N. D. Bowles and P. T. Bland for technical assistance.

Weak neutral current and β radiolysis effects on the origin of biomolecular chirality

Roger A. Hegstrom

Department of Chemistry, Wake Forest University, Winston-Salem, North Carolina 27109, USA

The possibility of a connection between the parity non-conserving weak interactions and the handedness of biomolecules has received recent attention[1]. Although the asymmetric effects of the weak interactions in molecules have been estimated to be very small[2–9], Kondepudi and Nelson (KN)[10–13] have shown that autocatalytic chemical systems that spontaneously break chiral symmetry[14–19] can effectively amplify systematic chiral perturbations as small as those produced by weak neutral currents[2–4,20], despite the simultaneous presence of larger randomly fluctuating chiral perturbations, and hence provide a mechanism for producing the observed homochirality of biomolecules. I show here, in the light of new estimates of the asymmetric decomposition of racemic mixtures by β radiation[9], that the chiral selection parameter due to β radiolysis can be up to six orders of magnitude larger than that resulting from weak neutral currents. This suggests that β radiolysis is more likely to be the selector of biomolecular chirality than weak neutral currents.

The same chemical kinetic model is used as in KN[10–13] but the reactants S and T in the model are taken to be chiral, rather than achiral as assumed by KN, and only homochiral combinations of reactants with each other and with the autocatalytically formed product X are assumed to occur, for example, $S_L + T_L + X_L \rightarrow 2X_L$; $S_D + T_D + X_D \rightarrow 2X_D$. Here S and T could be, for example, chiral monomers which react to form a dimer X. Alternatively, this simple model could be interpreted as an

abbreviated approximation of a more complicated mechanism for the formation of a polymer X. Because all known biomolecules capable of catalysing their own formation (the protein/nucleic acid systems) are polymers formed from homochiral monomers, the assumption of chiral reactants rather than achiral ones seems a reasonable modification of the original KN model considered as a description of the autocatalytic formation of prebiomolecules.

The kinetic model gives the expression $dX_L/dt = k_1S_LT_L - k_{-1}X_L + k_2S_LT_LX_L - k_{-2}X_L^2 - k_3X_LX_D$ for the rate of formation of X_L and a similar expression (with L and D interchanged) for formation of X_D, where S_L, T_L, and X_L denote molar concentrations of the corresponding substances. According to these equations, the enantiomers X_L and X_D are formed at different rates if the concentrations of reactants, assumed by KN[10-13] and in the present work to be constant or slowly varying in time, are such that S_LT_L is not equal to S_DT_D. The production of this inequality by asymmetric β radiolysis is considered below.

An inequality in constant reactant concentrations is equivalent to an inequality in rate constants. With the definitions $\eta = (S_L - S_D)/(S_L + S_D)$ and $S = (S_L - S_D)/2$ for reactant S, which imply $S_L = (1+\eta)S$ and $S_D = (1-\eta)S$, and with similar definitions for reactant T, the term $k_1S_LT_L$ appearing in the rate equation can be written correct to first order in η as $k_1(1+2\eta)ST = k_{1L}ST$, where it has been assumed for simplicity that η has the same value for both S and T, and where the last equation defines k_{1L}. Similarly, $k_1S_DT_D = k_{1D}ST$ with $k_{1D} = (1-2\eta)k_1$. In the same way as for k_1, the terms containing k_2 are replaced by ones containing $k_{2L} = (1+2\eta)k_2$ and $k_{2D} = (1-2\eta)k_2$. Finally, the selection parameter, defined by KN as $g = 2(k_{1L} - k_{1D})/(k_{1L} - k_{1D})$, is found to be related to η simply as $g = 4\eta$.

With the above definitions, the resulting rate equations are identical to those of the original KN model[10-13], but the physical origin of the asymmetries in the effective rate constants k_1 and k_2 is quite different. In the original KN model, weak neutral currents produce inequalities $k_{1L} \neq k_{1D}$ and $k_{2L} \neq k_{2D}$ which in typical organic molecules give a resulting selection parameter $g = \Delta E/RT \sim 10^{-17}$, where ΔE is the parity nonconserving energy difference between enantiomers[2-4]. In spite of its smallness, KN have demonstrated that this value of g is sufficiently large to determine the eventual dominance of one of the enantiomers of X (refs 10-13). For comparison, we now consider the production of concentration inequalities $S_L \neq S_D$ and $T_L \neq T_D$ by β radiolysis[5-9] of a racemic mixture of reactants (β radiolysis of X was also calculated and found to be less important). Here the value of η created by the asymmetric decomposition of the enantiomers depends on the strength of the β-ray source, the irradiation time, and the temperature. For organic compounds exposed to likely prebiotic sources of β radiation and temperatures below 80 °C, η has been estimated[9] to attain values as high as 10^{-12}. It follows from the relation $g = 4\eta$ that the value of g resulting from β radiolysis can be up to five or six orders of magnitude larger than the value of g resulting from weak neutral currents. This dominance by β radiolysis is also expected for most chiral molecules containing heavy atoms, where the values of g are predicted to be larger for both types of interaction[2-4,8].

Hence, it is predicted that β radiolysis can produce a much larger systematic chiral perturbation than produced by weak neutral currents. If a racemic mixture of reactants is exposed for a sufficiently long period of time to sufficiently strong β radiation sources such as those which may have been present in prebiotic times[9], and if a symmetry-breaking autocatalytic chemical reaction of the type analysed by KN[10-13] then occurs, the chirality of the resulting product is more likely to be determined by β radiolysis than by weak neutral currents. Provided that an effective autocatalytic chemical reaction can be realized, an experimental test of this prediction seems possible using existing intense sources of β radiation[9].

I thank A. Rich and J. Van House for discussions.

Osmotic stress mimics effects of vasopressin on learned behaviour

George F. Koob*, Robert Dantzer†, Floreal Rodriguez‡, Floyd E. Bloom* & Michel Le Moal†

It has been suggested that arginine vasopressin (AVP) is involved in the retention of learned responses, in addition to its classical physiological functions of water retention and modulation of blood pressure. AVP administered subcutaneously (s.c.), intraventricularly or intracerebrally can prolong extinction of active avoidance behaviour[1,2] and can enhance retention in inhibitory (passive) avoidance[3-5]. These effects have been interpreted as a direct action of AVP on the central nervous system to facilitate memory consolidation[3,4]. AVP also has facilitatory effects on cognitive function in humans[6], and marked deficits in AVP function have been associated with certain types of psychopathology[7]. Alternative hypotheses for the behavioural actions of AVP have involved motivational constructs such as arousal[8], and our recent work has focused on the role of arousal resulting from the activation of peripheral visceral signals in the behavioural effects of peripherally administered AVP[9-12]. The development of a specific antagonist for AVP[13], 1-deaminopenicillamine-2-*O*-methyl tyrosine arginine vasopressin (dPTyr(Me)AVP), which can reverse the behavioural effects of exogenously administered AVP[9-12], has provided a powerful tool for examining the role of AVP in the behavioural responses produced by physiological challenges known to release vasopressin. However, the relationship between the behavioural effects of exogenously administered AVP and the behavioural function of endogenously released AVP has not been evaluated. We report here that a potent peripheral osmotic stimulus, the intraperitoneal (i.p.) injection of hypertonic saline, at doses known to release AVP both centrally[14] and peripherally[15], will produce behavioural effects similar to those of exogenously administered AVP. Furthermore, the prolongation of active avoidance induced by this osmotic stimulus is reversed by pretreatment with dPTyr(Me)AVP, suggesting that endogenously released AVP may also produce behavioural effects.

Male Wistar rats (150-220 g), each handled and weighed once previously, were trained to avoid shock in a pole jump apparatus as described previously[2]. Briefly, during the initial training of the active avoidance response, the rats were subjected to 10 trials per day where a 5-s conditioned stimulus preceded a 0.3-0.5-mA footshock to the floor. A response during the 5-s conditioned stimulus (light illumination) was recorded as an

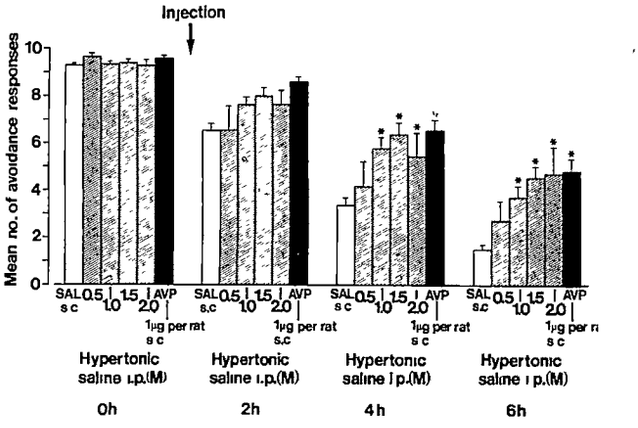

Fig. 1 Effects of different doses of hypertonic saline on extinction of active avoidance Rats were injected with saline i p immediately after the first 10 extinction trials on day 4 of testing. * Significantly different from the saline group, $P < 0.05$, Student's t-test following a significant overall analysis of variance for each separate extinction session. Numbers of subjects were 83, 11, 52, 34, 11 and 42 in the saline, 0.5 M, 1 0 M, 1 5 M, 2 0 M NaCl and AVP (1 μg per rat, ~5 4 μg per kg) groups, respectively

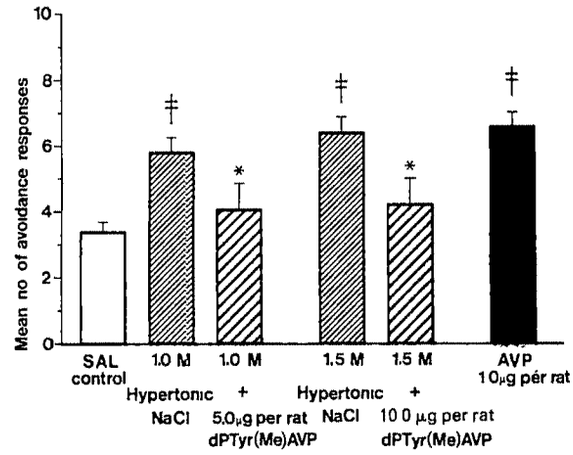

Fig. 2 Effects of the AVP antagonist on the prolongation of extinction produced by hypertonic saline. Data shown represent only those from extinction session III, but results from extinction session IV were identical. * Significantly different from hypertonic saline alone, $P < 0$ 05, Student's t-test following a significant overall analysis of variance for each logical grouping; ‡ significantly different from saline, $P < 0.05$. Numbers of subjects were 83, 52, 21, 34, 10 and 42 for the saline, 1.0 M NaCl only, 1.0 M NaCl + 5.0 μg per rat (~27 μg per kg) dPTyr(Me)AVP, 1 5 M NaCl only, 1.5 M NaCl + 10 μg per rat (~54 μg per kg) dPTyr(Me)AVP, and AVP, respectively. Saline, 1.0 M NaCl, 1.5 M NaCl and AVP groups are the same as in Fig. 1 for extinction session III.

avoidance and the inter-trial interval was 40, 60 or 80 s, randomly assigned across trials. Following 3 days of acquisition, rats were subjected to a fourth day of extinction testing with all conditions identical except that the shock was turned off. Only those rats meeting the previously established acquisition/extinction criteria[1,2] were treated; these rats all showed ≥14 successful avoidance responses during acquisition and ≥8 avoidances during the first 10 extinction trials. Only these animals were used in the experiment. This criterion was similar to that used by De Wied and associates[1] and eliminated 10% of the rats. Four blocks of 10 trials each were run; after the first 10 trials, each rat was treated with either 0.9% saline s.c., 1 μg of vasopressin dissolved in 0.9% saline, or different concentrations of hypertonic saline (0.25–2.0 M) injected i.p. in a volume of 2 ml.

Extinction testing was continued for three more blocks of 10 trials, one block every 2 h. Drinking water was available during the testing period. In a second experiment, the procedure was identical except that rats received two injections immediately after the first 10 trials of extinction: 0.9% saline or the AVP pressor antagonist was injected s.c.[13], followed immediately by 1.0 or 1.5 M NaCl as an osmotic stimulus. All testing was done under 'blind' conditions, that is, the experimenter did not know which rats received which treatments. Each 4-day testing series consisted of 20 rats randomly assigned to the treatment groups. Each series always contained rats receiving 0.9% saline and AVP s.c., and groups receiving hypertonic saline injections combined with the antagonist were always tested with a group receiving hypertonic saline alone. As a result, many more rats were included in the 0.9% saline (control) group and the AVP group.

The hypertonic saline was injected i.p. to replicate previous studies which measured AVP levels and plasma osmolality. These doses are similar to those used by others[15] to show dose-dependent increases in plasma osmolarity and plasma AVP levels. In that study, a dose identical to our 1.0 M NaCl dose in rats of the same weight produced plasma osmolarity of 305 mosm per kg and a plasma AVP level of 10 pg ml^{-1}. Measurements of AVP in the blood in our laboratory (S. Deyo, W. J. Shoemaker, A. Ettenberg, F.E.B. and G.F.K., unpublished results) revealed plasma levels of 13.1 ± 2.2 to 28.4 ± 3.5 pg ml^{-1} 20 min after s.c. injection of behaviourally effective doses of AVP (0.1–1.0 μg per rat). Thus, the osmotic stimuli used here produce plasma AVP levels within the range of those produced with exogenous injection. A similar osmotic challenge (2 and 4 ml of 2 M NaCl) in anaesthetized rats provoked a dramatic increase in AVP release into a push-pull cannula localized to the lateral septum[14].

Hypertonic saline injection produced a dose-dependent prolongation of active avoidance, reaching significance at doses of 1.0 and 1.5 M NaCl (Fig. 1); data from 0.25 M NaCl were not different from controls and are not shown. These results were virtually identical to those produced by 1 μg AVP injected s.c. Following the injection of hypertonic saline, the rats showed some irritability and occasionally some vocalization, but these effects disappeared within 2–3 min. Note that the rats receiving this hypertonic saline injection showed no greater ill effects than those observed following AVP. For example, exogenously administered AVP in behaviourally effective doses produces taste aversions in rats[12] and hypertonic saline at the higher doses used in these avoidance experiments (1.5 and 2.0 M NaCl) produced similar taste aversions (R.D. and G.F.K., unpublished results).

At 5 μg per rat, the vasopressin antagonist produced an attenuation of this effect of hypertonic saline (Fig. 2). A similar reversal was seen with 10 μg antagonist after treatment with 1.5 M NaCl (Fig. 2). Preliminary results indicate that this effect may be dose-dependent, in that 2.5 μg antagonist did not attenuate the prolongation of extinction produced by 1 M NaCl (mean ± s.e.m., number of avoidances for extinction session III were 5.90 ± 1.17 for 2.5 μg per rat compared with 5.79 ± 0.49 for 0 μg per rat).

These results demonstrate that an interoceptive osmotic challenge (hypertonic saline), known to release AVP, can mimic the effects of exogenous AVP on learned behaviour. Further, this behavioural effect is reversed by an AVP receptor antagonist, suggesting a causal relationship between the endogenously released AVP and the behavioural change. Similar doses of the AVP antagonists have been used to reverse the behavioural effects of exogenously administered AVP in various learning tasks[9–10].

It is unlikely that the antagonist effect in the present experiment is due to an action of the antagonist itself, independent of endogenously released AVP, for example by a general sedative or tranquillizing action. Except for the 100 μg dose[2], we have observed no effect with this antagonist in reversing prolongation of active avoidance produced by high shock levels during training. Also, the AVP antagonist did not significantly alter caffeine-stimulated locomotion at doses from 2.5 to 10 μg per rat (~17–67 μg per kg, see Table 1*a*). Analysis of variance of these data

Table 1 Effects of AVP antagonist dPTyr(Me)AVP on caffeine-stimulated locomotor activity (*a*) and performance in a multiple-schedule operant conflict test (*b*)

		dPTyr(Me)AVP dose		
a	Saline	2.5 μg (17 μg per kg)	5.0 μg (33 μg per kg)	10.0 μg (67 μg per kg)
	1,238 ± 103 $n = 6$	1,032 ± 145 $n = 6$	1,512 ± 283 $n = 5$	1,487 ± 294 $n = 7$
			dPTyr(Me)AVP dose	
b	Component	Saline	10 μg (27 μg per kg)	20 μg (54 μg per kg)
	Random interval 30-s schedule	108 ± 18	117 ± 18	111 ± 29
	Conflict	122 ± 30 $n = 5$	113 ± 19 $n = 5$	113 ± 22 $n = 5$

a, Activity was measured automatically in standard photocell activity cages in continuous 10-min epochs for 90 min following injection of dPtyr(Me)AVP s.c. and 10 mg per kg caffeine (base). For details see ref. 30 *b*, Food-deprived rats previously trained on the conflict multiple schedule were given dPTyr(Me)AVP s.c. 5 min before an 18-min test session. Schedule and testing procedure are described in ref 16

showed no dose effect and no dose × time interaction (both $F < 1$). The AVP antagonist also failed to produce any sedative-like actions in an operant Geller-Seifter conflict test[16] that is very sensitive to minor tranquillizers. It did not alter high-rate responding maintained by the random interval 30-s schedule, and also failed to produce a release of punished responding in the conflict component (Table 1*b*). Finally, the antagonist did not reverse apomorphine-induced taste aversion (R.D., R. M. Bluthe, G.F.K. and M. Le M., unpublished observations). Although it is possible that the hypertonic saline produced elevations in blood pressure that contributed to the behavioural effects, NaCl-induced changes in blood pressure are also reversed by these vasopressor AVP antagonists[17], indicating that such a role for pressor responses as an intervening variable with NaCl would be similar to that seen with exogenously administered AVP[12].

Finally, these and other recent data[9-12] reopen the question of the nature of brain-pituitary interactions. One unresolved problem concerns the mechanism mediating this AVP behavioural response. For example, there is little evidence that AVP itself crosses the blood-brain barrier, particularly at doses that would be liberated from the pituitary in the conditions of the present experiment[18-22]. Furthermore, central AVP pathways exist independently of the classical hypothalamo-posterior pituitary projection[23], and both central and peripheral AVP are released by the osmotic challenge used here[14,15]. De Wied and co-workers have argued for a central site of action based on the observation that a new analogue of vasopressin (pGlu^4, Cyt^{6}AVP(4-8)), when injected peripherally, is much more active than AVP itself in facilitating passive avoidance[24]. This analogue has no pressor activity and its effects can be reversed by an even more potent AVP pressor antagonist[25] injected in nanogram amounts intracerebroventricularly. Our earlier work showed that dPTyr(Me)AVP can reverse the effects of centrally administered AVP[26], but will only reverse the behavioural effects of peripherally injected AVP when injected centrally in doses sufficient to reverse the peripheral pressor effects of the same doses[27,28]. From this we hypothesize an effect of AVP from both central and peripheral sources acting independently but in a homologous fashion[29]. Thus, in the present experiment, the behavioural change following osmotic challenge could result from a release of AVP from the pituitary and/or the central nervous system.

These results also have important implications for our conceptualization of the role of AVP in behaviour and of brain-body interactions in learning. Clearly, an AVP reserve sufficient to change or even mobilize behaviour, is available in situations of extreme challenge. It will be critical to determine whether other cues can activate this sytem, and how this mechanism works, if at all, in normal behaviour.

We thank Dr Jean Rivier for providing AVP and dPTyr(Me)AVP; Rose-Marie Bluthe, Jean Mexmain and Achim Raab for help with testing the rats; and Nancy Callahan for manuscript preparation. Bidirectional control of cytosolic free calcium by thyrotropin-releasing hormone in pituitary cells

Alan H. Drummond

Department of Pharmacology, University of Glasgow, Glasgow G12 8QQ, UK

It is now established that a key step in the action of calcium-mobilizing agonists is stimulation of the hydrolysis of phosphatidylinositol 4,5-bisphosphate (PtdIns(4,5)P_2) to 1,2-diacylglycerol and inositol 1,4,5-trisphosphate (InsP_3)[1,2]. The latter substance acts as a second messenger, controlling the release of calcium from intracellular stores (see ref. 3 for review). The bifurcating nature of the signalling system is exemplified by the fact that the other product of PtdIns(4,5)P_2 hydrolysis, 1,2-diacylglycerol, can alter cellular function by activating protein kinase C, the cellular target for several tumour-promoting agents such as the phorbol esters[4,5]. In various tissues, including GH_3 pituitary tumour cells, a synergistic interaction between calcium ions and protein kinase C underlies agonist-induced changes in cell activity[4,6-10]. The data presented here suggest that when GH_3 cells are stimulated by thyrotropin-releasing hormone (TRH), an agonist inducing PtdIns(4,5)P_2 hydrolysis[11-14], the two limbs of the inositol lipid signalling system interact to control free cytosolic calcium levels ($[Ca^{2+}]_i$). At low levels of TRH receptor occupancy, $[Ca^{2+}]_i$

increases rapidly, then declines relatively slowly. As receptor occupancy increases, the calcium signal becomes more short-lived due to the appearance of a second, inhibitory, component. This latter component, which is enhanced when $[Ca^{2+}]_i$ is elevated by high potassium depolarization, is mimicked by active phorbol esters and by bacterial phospholipase C. It seems likely that protein kinase C subserves a negative feedback role in agonist-induced calcium mobilization.

When TRH was added to GH_3 cells which had been preloaded with the fluorescent calcium indicator, Quin-2 (ref. 15), there was a rapid increase in fluorescence, indicative of an elevation in $[Ca^{2+}]_i$ (refs 16-20). Figure 1*a* shows, in confirmation of previous results[20], that the kinetics of the TRH-stimulated calcium signal is concentration-dependent; low concentrations of TRH (10^{-9} M) stimulate a relatively long-lived response, while higher concentrations of the peptide give a larger, more transient response. The reversal of the calcium signal with elevated TRH concentrations was more readily seen when the peptide was added following stimulation with high KCl, which has been shown to increase $[Ca^{2+}]_i$ by opening voltage-sensitive calcium channels[16-19,21,22]. Low concentrations of TRH had no effect in these conditions, while with higher concentrations, an initial increase in fluorescence was rapidly superceded by an inhibitory component (Fig. 1*b*). The calcium dependence of the inhibitory mechanism is examined in the experiments summarized in Fig. 1*c*. Pre-stimulation with different concentrations of KCl allows $[Ca^{2+}]_i$ to be titrated to various levels. In the experiment shown in Fig. 1*c*, the $[Ca^{2+}]_i$ values immediately before TRH addition were 110, 205 and 440 nM when the concentration of the depolarizing stimulus was 5, 20 and 40 mM KCl, respectively. Subsequent addition of TRH (10^{-7} M) led to a marked inhibitory effect only with 40 mM KCl (Fig. 1*c*).

There is considerable evidence that phorbol esters activate cellular processes by mimicking the effects of 1,2-diacylglycerol on protein kinase C[5,23-25]. Addition of active phorbol esters such as 4β-phorbol 12-myristate 13-acetate (PMA, 10^{-9}-10^{-6} M) to GH_3 cells had no significant effect on the resting $[Ca^{2+}]_i$ (Fig. 2) or on the cellular content of $InsP_3$ (Fig. 2 legend). Addition of PMA (10^{-6} M) to GH_3 cells 5 min before the addition of TRH resulted in a partial inhibition of the TRH-induced rise in $[Ca^{2+}]_i$ (Fig. 2) and a reduction in the ability of the peptide to increase $InsP_3$ levels (Fig. 2 legend). The inhibition of both responses was especially marked when low concentrations of TRH (10^{-10}-10^{-9} M) were used.

When PMA (5×10^{-7} M) was added to GH_3 cells previously stimulated with 40 mM KCl, $[Ca^{2+}]_i$ decreased after a lag of 30 s (Fig. 3*a*). This inhibitory effect, unlike that following TRH addition (Fig. 3*a*), was not preceded by an increase in $[Ca^{2+}]_i$. Other phorbol esters such as 4β-phorbol 12,13-didecanoate also produced a reduction in $[Ca^{2+}]_i$ in the above conditions, whereas agents which are inactive or only weakly active in stimulating protein kinase C[5,26-28], such as 4β-phorbol or 4α-phorbol 12,13-didecanoate, were inactive at concentrations of 2×10^{-6} M (data not shown).

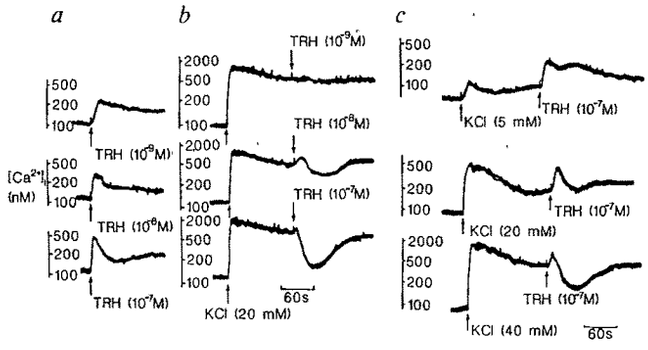

Fig. 1 Effect of TRH on cytosolic free calcium levels in untreated GH_3 cells and in GH_3 cells previously exposed to depolarizing concentrations of KCl *a*, Response of Quin-2-loaded GH_3 cells to different TRH concentrations Note that the decay of the calcium signal is considerably enhanced with high concentrations of the peptide. *b*, Response when TRH was added 2 min after addition of a depolarizing concentration of KCl Addition of a similar concentration of NaCl had no effect on $[Ca^{2+}]_i$. *c*, GH_3 cells were exposed to different concentrations of KCl before the addition of TRH. Note that TRH had a marked inhibitory effect only when the highest concentration of the depolarizing stimulus was used **Methods.** GH_3 cells were grown as described previously[13] in Ham's F10 medium supplemented with antibiotics, horse serum and fetal calf serum. For all experiments, the cells to be used were suspended in a balanced salt solution (BSS)[13]. Cytosolic free calcium was estimated using Quin-2[15] Cells ($3-5\times10^6$ ml^{-1}), loaded with 2×10^{-5} M Quin2/AM, the tetraacetoxymethyl ester of Quin-2, for 15 min at 37 °C, were washed twice in BSS and stored until use at room temperature in a darkened container. Immediately before use, the cell samples were centrifuged (14,000 *g*, 5 s) and resuspended in fresh BSS (pre-equilibrated at 37 °C) at a cell concentration of $3-5\times10^6$ ml^{-1}. Fluorescence measurements were made at 37 °C on stirred samples (2 ml) of these cells using a Perkin-Elmer LS-3 spectrophotofluorimeter; excitation wavelength, 339 nm, emission wavelength, 492 nm. At the end of the analysis, 5×10^{-5} M digitonin was added to measure the maximum fluorescence (F_{max}) and then excess alkaline EGTA was added to measure minimum fluorescence (F_{min}) The values of $[Ca^{2+}]_i$ were calculated from the equation: $[Ca^{2+}]_i = K_D\times(F-F_{min})/(F_{max}-F)$, taking a value of 115 nM as the K_D of Quin-2 for Ca^{2+} (ref 15) Neither TRH nor any of the other drugs used in this study had any effect on the fluorescence of GH_3 cells which had not been loaded with Quin-2 (data not shown).

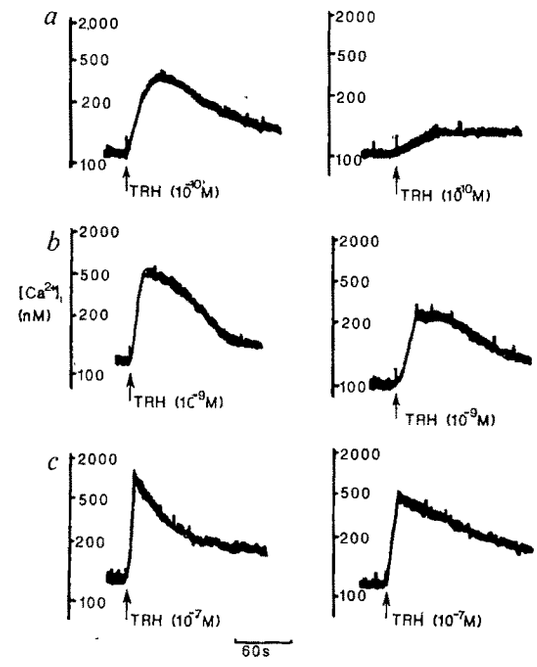

Fig. 2 Effect of 4β-phorbol 12-myristate 13-acetate (PMA) on basal and TRH-stimulated cytosolic free calcium levels in GH_3 cells The cytosolic free calcium concentration of Quin-2-labelled GH_3 cells was measured as described in Fig. 1 legend. The traces in *a*, *b* and *c* show the effects of preincubation of GH_3 cells for 5 min with dimethyl sulphoxide (vehicle of PMA, 0.1% (v/v) left) or PMA (10^{-6} M) (right) Dimethyl sulphoxide, at this concentration, did not alter the basal level of $[Ca^{2+}]_i$ or affect the response of the cells to TRH (data not shown). Note that although PMA did not significantly reduce basal levels of $[Ca^{2+}]_i$ in GH_3 cells, it did reduce the response (and, in particular, the rate of rise) to TRH (10^{-10}-10^{-7} M). The GH_3 cell content of $InsP_3$, measured as described in Table 1 legend, was unaffected by 5 min preincubation with PMA (10^{-6} M) (4,622 ± 533 d p.m. per sample, control; 4,517 ± 286 d p.m. per sample, PMA-treated). This value rose within 5 s of TRH addition to 5,866 ± 177 (10^{-9} M TRH) and 9,777 ± 711 (10^{-7} M TRH) d.p.m. per sample. Corresponding values in PMA-treated cells were 5,016 ± 187 (5 s, 10^{-9} M TRH) and 6,933 ± 177 (5 s, 10^{-7} M TRH) d p m. per sample.

Table 1 Effect of bacterial phospholipase C on the GH_3 cell content of 1,2-diacylglycerol and inositol trisphosphate

Addition	Incubation time (s)	1,2-Diacylglycerol (d.p.m. per sample)	$InsP_3$
Control	—	1,756±80	1,079±182
Phospholipase C (0.1 U ml^{-1})	180	7,756±869*	1,278±100

Phospholipase C (2.5 U ml^{-1})	180	36,450±1610*	2,872±282†

The GH_3 cell content of 1,2-diacylglycerol and $InsP_3$ was measured in cells which had been pre-labelled to isotopic equilibrium with ^{3}H-glycerol (25 μCi per dish) or ^{3}H-inositol (5 μCi per dish) respectively. The methods have been described previously[13,14]. Briefly, GH_3 cell suspensions (0.5 ml), pre-labelled for 3–4 days with ^{3}H-glycerol or ^{3}H-inositol (Amersham International), were incubated with phospholipase C (from *Clostridium perfringens*, Sigma lot 53F-9007) for the times indicated The reaction was stopped by the addition of 1.5 ml chloroform/methanol (1:2 v/v; for 1,2-diacylglycerol extraction) or 0.5 ml 20%(w/v) trichloroacetic acid (for $InsP_3$ estimation). The cell content of the two products of $PtdIns(4,5)P_2$ hydrolysis were then measured as outlined in refs 13 and 14 In different experiments, the samples of cell suspension contained 0.4–0.6 mg of cellular protein. The values shown are the means±s.e m. for three or four samples.

* $P<0.001$; † $P<0.01$, significantly different from the untreated control

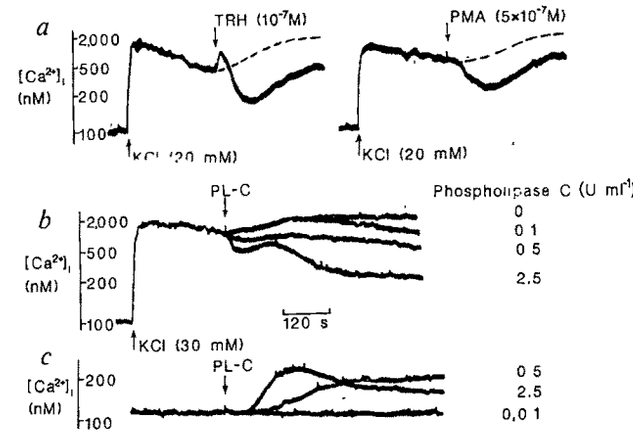

Fig. 3 Effect of agents that stimulate protein kinase C activity on cytosolic free calcium levels in GH_3 cells. The cytosolic free calcium concentration of Quin-2-labelled GH_3 cells was monitored as described in Fig. 1 legend. The traces in *a* show representative responses of GH_3 cells to the addition of TRH and PMA. The dotted line indicates the control response Note that the phorbol ester elicited a reduction in $[Ca^{2+}]_i$ without a preceding rise. *b*, *c*, Effect of addition of bacterial phospholipase C (PL-C) The enzyme (from *C perfringens*, Sigma lot 53F-9007) elevated $[Ca^{2+}]_i$ itself after a lag of ~60 s (panel *c*) when high activities were used. In cells whose $[Ca^{2+}]_i$ had previously been elevated with KCl, phospholipase C induced a reduction in the level of the cation (panel *b*). The onset of the response was dependent on the activity of the enzyme used. Corresponding changes in the cell content of 1,2-diacylglycerol and $InsP_3$ are shown in Table 1

Addition of bacterial phospholipase C to GH_3 and various other cells stimulates 1,2-diacylglycerol formation and activates protein kinase C-dependent protein phosphorylation and cellular responses[9,29–32]. We found that low activities of the enzyme (≤100 mU ml^{-1}) led to a reduction in $[Ca^{2+}]_i$ after a lag of 3 min (Fig. 3*b*). At this time, cellular 1,2-diacylglycerol levels increased significantly, with no change in $InsP_3$ content (Table 1) and, as reported elsewhere[32], protein kinase C-dependent protein phosphorylation also increased. Higher enzyme activities led to more rapid increases in 1,2-diacylglycerol content in the absence of changes in cell $InsP_3$ levels (Table 1), and this was also associated with a decrease in $[Ca^{2+}]_i$ (Fig. 3*b*). When the incubation time was lengthened, however, phospholipase C (>500 mU ml^{-1}) did elicit an elevation in $InsP_3$ (Table 1). As might be expected from the effects of $InsP_3$ on various cells[3], this was associated, in the absence of depolarization, with a rise in $[Ca^{2+}]_i$ (Fig. 3*c*) or, in the presence of depolarization, with a temporary stabilization of $[Ca^{2+}]_i$ (Fig. 3*b*).

There is now strong evidence that TRH, acting on GH_3 cells, produces the initial rise in $[Ca^{2+}]_i$ by a mechanism dependent on $InsP_3$-stimulated release of intracellular calcium[20,33]. Other studies show that this mechanism is fully activated at relatively low levels of receptor occupancy[20]. The second, inhibitory, mechanism, which predominates at high levels of receptor occupancy, seems to be under the control of protein kinase C, as it can be mimicked by treatments that activate the enzyme in the conditions used. Moreover, at the time the inhibitory phase is becoming evident, 1,2-diacylglycerol levels have already been elevated by TRH[12,13]. It is possible that the inhibitory mechanism is effected by: (1) stimulating the intracellular sequestration of calcium, (2) stimulating calcium extrusion from the cell, (3) inhibiting calcium mobilization or (4) blocking calcium entry across the plasma membrane. The latter two explanations seem unlikely, as the inhibitory effect occurs with either TRH or depolarization as the stimulus for calcium elevation; there is good evidence[16,21] that the source of calcium differs in the two cases, with intracellular calcium the source for the TRH effect and influx of extracellular calcium the mechanism by which high K^+ elicits its effect. Indeed, the TRH-induced calcium signal still fades rapidly with high concentrations of the peptide in the presence of 2 mM EGTA (data not shown). It is evident, nevertheless, that activators of protein kinase C can inhibit the TRH-induced rise in $InsP_3$ and $[Ca^{2+}]_i$ in GH_3 cells and diminish calcium mobilization and phosphatidate accumulation in other cells[34,35]. It is unlikely, however, that this effect underlies the inhibitory phase of TRH action because: (1) this phase is mimicked by phorbol esters in conditions in which no $InsP_3$ formation occurs (with high K^+ as the stimulus), (2) levels of $InsP_3$ remain elevated in response to TRH for at least 30 min after peptide addition, although the calcium signal fades rapidly with high concentrations of TRH[36] and (3) such a block of $InsP_3$ production cannot reasonably explain why TRH is able to decrease $[Ca^{2+}]_i$ below the elevated steady-state value achieved after high K^+ depolarization; only the increment due to TRH would be expected to be reversed by this mechanism. It seems likely that the inhibition of $InsP_3$ formation represents an additional mechanism which may have a general role in limiting information flow through the inositol lipid signalling system in chronically stimulated cells, rather than over the initial seconds of the agonist-induced response. The most plausible mechanism for the inhibitory phase of TRH action, as studied here, is that sequestration or extrusion of the cation is facilitated by protein kinase C. ATP-dependent calcium transport across both intra- and extracellular membranes has been reported to be sensitive to protein kinase C[37,38]. Further work is under way to clarify this point.

Whatever the mechanism, it is evident that both elevated $[Ca^{2+}]_i$ and 1,2-diacylglycerol levels are required for the negative feedback system to operate effectively. This suggests that the mechanism by which calcium is removed must be primed with an appropriate amount of calcium before it can be modulated by protein kinase C—an elegant and economical way of buffering excessive changes in $[Ca^{2+}]_i$ after agonist stimulation. These data demonstrate the flexibility of control which is a major advantage of the bifurcating inositol lipid signalling system.

I thank the Medical Research Funds of the University of Glasgow and the Wellcome Trust for supporting this work.

Intracellular Ca indicator Quin-2 inhibits Ca^{2+} inflow via Na_i/Ca_o exchange in squid axon

T. J. A. Allen & P. F. Baker

Laboratory of the Marine Biological Association, Plymouth PL1 2PB and Department of Physiology, King's College, Strand, London WC2R 2LS, UK

Until recently, intracellular free calcium has been amenable to measurement and investigation only in cells large enough to permit either microinjection of a suitable Ca sensor such as aequorin or arsenazo III or insertion of a Ca-sensitive microelectrode[1,2]. This constraint on cell size was removed by the development of the fluorescent Ca^{2+}-sensitive dye Quin-2 and its acetoxymethyl ester, which can be introduced into a wide range of cell types[3,4]. A major requirement of any intracellular Ca^{2+} indicator is that it should not disturb intracellular Ca^{2+} homeostasis and Quin-2 is generally considered to be satisfactory in this respect[5]. We now report that injection of Quin-2 into squid (*Loligo forbesi*) axons can almost completely abolish one component of Ca^{2+} entry—intracellular Na^+ (Na_i)-dependent Ca^{2+} inflow, which occurs via Na/Ca exchange[6]. Mixtures of Ca and Quin-2 that buffer an ionized Ca^{2+} at close to physiological concentrations also block Na_i-dependent Ca^{2+} influx but these same mixtures fail to block the extracellular Na^+ (Na_o)-dependent extrusion of Ca^{2+}, showing that Quin-2 acts specifically on Ca^{2+} inflow.

Depending on the size and direction of the electrochemical gradient for Na^+, the Na/Ca exchange system can effect net movement of Ca^{2+} either into or out of the cell. For squid axons the exchange fluxes are most easily monitored either as the Ca_o-dependent ^{22}Na efflux (Ca_o/Na_i exchange mode) or the Na_o-dependent ^{45}Ca efflux (Na_o/Ca_i exchange mode)[2]. Because external Na^+ and Ca^{2+} compete for the exchanger, Ca_o-dependent ^{22}Na efflux is most conspicuous in Na^+-loaded axons immersed in Na^+-free media[6], although a small component is detectable in physiological conditions. Figure 1 shows an experiment in which both the Ca_o-dependent ^{22}Na efflux (Ca_o/Na_i exchange) and the K_o-dependent ^{22}Na efflux (Na/K exchange pump) were monitored before and after injection of Quin-2 to give a final axoplasmic Quin-2 concentration of ~300 μM. Within 2 min of injecting the Quin-2, the Ca_o-dependent ^{22}Na efflux started to fall and after 10 min <10% of the initial Ca_o-dependent ^{22}Na efflux was detectable. Subsequent examination of the K_o-dependent ^{22}Na efflux revealed that the Na/K pump was essentially unaltered, showing that Quin-2 selectively inhibits the Ca_o/Na_i exchange flux. Essentially similar results were obtained with final axoplasmic Quin-2 concentrations as low as 150 μM. Inhibition by Quin-2 is not confined to the Ca_o-dependent ^{22}Na efflux: the associated Ca^{2+} influx is also

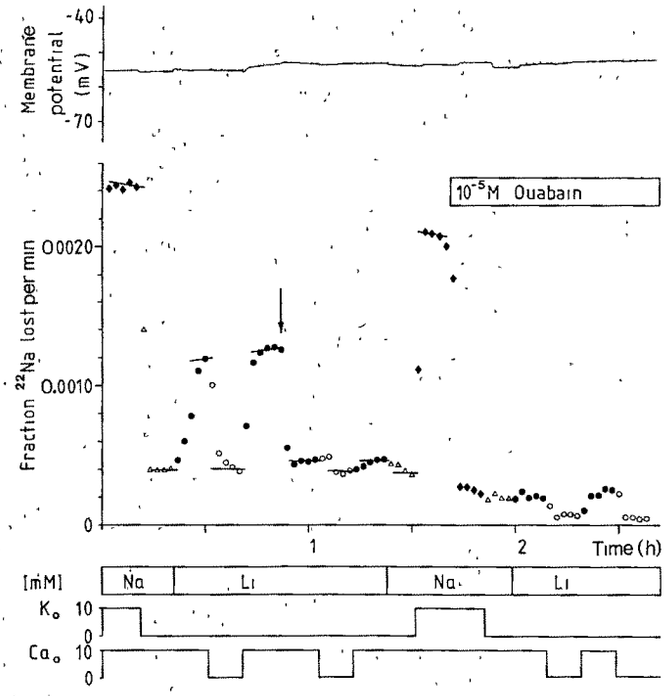

Fig. 1 Effect of Quin-2 injection on the various components of the ^{22}Na efflux from an axon of *Loligo forbesi*. The magnitude of the sodium pump flux was first determined as the reduction of the ^{22}Na efflux brought about by removing external K^+. In the absence of K^+, subsequent iso-osmotic replacement of NaCl by LiCl activates the ^{22}Na efflux and the whole of this activated flux is dependent on external Ca^{2+}. Injection of Quin-2 selectively inhibits the Ca_o-dependent ^{22}Na efflux, because subsequent re-introduction of potassium still activates a large ouabain-sensitive ^{22}Na efflux. The different symbols reflect solution changes, as indicated at the bottom

Methods. After dissecting away the surrounding small nerve fibres, the giant axon was cannulated and injected with a small patch of ^{22}Na. The injector was removed, loaded with 10 mM Quin-2 (tetrapotassium salt; Calbiochem) in 100 mM MOPS buffer, *p*H 7.4 and reinserted. Sampling of ^{22}Na in the superfusate began 65 min after injection of isotope. The membrane potential was monitored continuously by means of an axial intracellular microelectrode. At the time indicated by the arrow, Quin-2 was injected so that the column of Quin-2 overlapped the region of axon containing ^{22}Na. The artificial sea water contained 400 mM NaCl, 100 mM $MgCl_2$, 2.5 mM $NaHCO_3$, *p*H 7.8 with potassium and calcium as indicated. Periods for which NaCl was replaced iso-osmotically by LiCl are indicated at the the bottom, and the membrane potential (uncorrected for any junction potential) at the top. The axon was from a squid killed at sea and brought to the laboratory in refrigerated sea water; this results in appreciable Na^+-loading of the axon, which increases the size of the Ca_o/Na_i exchange flux[6]. Axon diameter 880 μm. Temperature 17 °C.

inhibited Thus the Ca^{2+} influx into control axons preinjected with morpholinopropanesulphonic acid (MOPS; 3.5 mM final concentration, *p*H 7.4) and subsequently immersed in Li-seawater was reduced to 25% of its initial value after injection of the same buffer containing Quin-2 to give an axoplasmic Quin-2 concentration of ~350 μM. As Na_i/Ca_o exchange is only one component of the measured Ca^{2+} influx, this may reflect a larger inhibition of the Na_i/Ca_o exchange moiety.

It has been known for some years that injection of EGTA into axons can inhibit Ca_o-dependent ^{22}Na efflux and the associated Ca^{2+} influx[7,8], and the data of Fig. 1 shows that the chemically related Quin-2 closely resembles EGTA in this respect. Both Quin-2 and EGTA are still effective inhibitors when injected with sufficient calcium to give a buffered free Ca^{2+} concentration close to the physiological value of 100 nM. Tests with other chelators revealed that injection of BAPTA (bis(*O*-aminophenoxy)ethane-*N*, *N*, *N'*, *N'*-tetraacetic acid), EDTA or NTA (nitrilotriacetic acid) to give a final axoplasmic concentration in the range 0.5–1.0 mM also inhibits selectively the Ca_o/Na_i exchange. In the same concentration range, arsenazo III exhibits a transient inhibition only. Of particular interest is the finding that injection of the chelator 1,2-dihydroxybenzene-3,5-disulphonate (Tiron), 1 mM final concentration), which has a very low affinity for Ca^{2+} but fairly high affinity for many heavy metal divalent cations[9], fails to block Ca_o/Na_i exchange. Although this result suggests that those chelators which block do so by stabilizing free Ca^{2+} and not by removing another essential divalent cation[10], other possibilities are not completely excluded.

While the present experiments demonstrate that calcium-chelators can block Na^+ and Ca^{2+} movements via Ca_o/Na_i exchange, the same chelators have little or no effect on Na_o/Ca_i exchange. Thus, injection of a mixture of 50 mM Quin-2 and 25 mM $CaCl_2$, which buffers the free Ca^{2+} close to the physiological concentration, does not alter the properties of the Na_o-dependent ^{45}Ca efflux (Na_o/Ca_i exchange). Essentially similar results are seen after injection of Ca^{2+}-EGTA mixtures. It would seem that Ca_o/Na_i exchange is particularly vulnerable to inhibition by intracellular chelators.

Experiments on dialysed axons provide a possible explanation for these findings[11]. Ca_o/Na_i exchange requires micromolar amounts of intracellular for Ca^{2+} for activation. It is unknown why Ca_i is needed to promote Ca^{2+} inflow but it seems to constitute a form of positive feedback which can be disrupted by the presence within the cell of a strong chelator[2].

These findings have two important implications: (1) experiments on Quin-2-loaded cells may fail to reveal Ca^{2+} inflow via Ca_o/Na_i exchange, especially when the Quin-2 level in the cell is ≥150 μM, which is quite common in Quin-2 studies. (2) Loading cells with millimolar amounts of Quin-2 (as the acetoxymethyl ester) might provide a relatively simple means of effecting selective inhibition of the Ca_o/Na_i exchange mode of the Na/Ca exchanger, it might, for example, be a useful way of examining the contribution of the Ca_o/Na_i exchange system, which is known to be voltage-sensitive[12], to ionic currents in tissues such as the heart.

We thank the MRC for financial support.

Expression of a mammalian Na–H exchanger in muscle fibres of the giant barnacle

It is now well established that the internal *p*H (*p*H$_i$) of mammalian cells is regulated by means of a plasma membrane transport system that exchanges extracellular Na^+ for intracellular H^+ (ref. 1). Furthermore, modulation of the activity of the Na–H exchanger seems to have a crucial role in the action of various mitogens and growth factors[2–4]. The possibility that such a mammalian Na–H exchanger might be efficiently expressed in a giant invertebrate cell was suggested to us by recent results of Barnard[5] and Miledi and colleagues[6,7], who demonstrated in frog oocytes the expression of various plasma membrane channels that presumably were encoded by the mammalian messenger RNA with which the oocytes had been injected. We used muscle fibres of the giant barnacle, which normally have no demonstrable Na–H exchanger activity[8], and report here that, when injected with poly(A)$^+$ RNA isolated from rabbit liver, the muscle fibres express a Na–H exchanger. No such expression is observed, however, when the injected material is pretreated with ribonuclease A. As hepatocytes are known to possess a Na–H exchanger[9], the most straightforward interpretation of our data is that a mammalian Na–H exchanger has been expressed in the muscle fibre of an invertebrate.

Muscle fibres of the giant barnacle (*Balanus nubilis*) were isolated as described previously[10], with one end of the fibre attached to the shell and the opposite (tendon) end free. The tendon of an individual fibre was cannulated, and through this cannula a glass injection pipette (~125 μm diameter) was advanced about 3 cm into the muscle, along the fibre's longitudinal axis. As the injection pipette was withdrawn from the fibre, fluid was deposited in the cell at the rate of ~1 μl per cm of fibre length. Fibre diameter was ~1 mm. In the first series of experiments, the injected material contained ~1 μg μl^{-1} of poly(A)$^+$ RNA (for a total dose of 3 μg RNA per fibre), isolated from rabbit liver as described in Fig. 1 legend. After the injection, the muscle fibre was incubated in artificial sea water (ASW) at 16 °C for ~18 h. Immediately before the assay for Na–H exchange, the fibre was soaked for ~15 min in Ca-free ASW, and then severed at the tendon and shell ends. The central portion of the fibre, ~2.5 cm in length, was transferred to a standard internal-dialysis chamber, cannulated at both ends. A length of dialysis tubing was inserted through one cannula, down the length of the fibre, and out of the opposite cannula. By perfusing this tubing with dialysis fluid of known composition, we were able to achieve good control over the intracellular environment[11]. A *p*H-sensitive microelectrode of the design of Hinke[12] was inserted through one cannula, and its tip advanced to the centre of the fibre. An open-tipped reference electrode filled with 3 M KCl was advanced similarly through the opposite cannula, permitting the continuous monitoring of pH_o, which was plotted on a strip-chart recorder. The actual assays for Na–H exchanger activity were performed in Ca-containing ASW.

Our strategy for detecting a mammalian Na–H exchanger in barnacle muscle was to block selectively the fibre's normal pH_i-regulating system. Regulation of pH_i in this cell[10,13,14], as well as in giant cells from molluscs[15,16], is mediated by a plasma membrane transport system that seems to exchange external

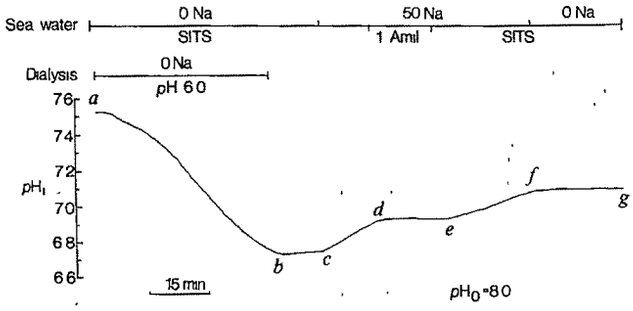

Fig. 1 pH_i recovery in a barnacle muscle fibre injected with poly(A)$^+$ RNA. See text for a detailed explanation of the experiment. The *p*H 7.4 dialysis fluid (DF) had the following composition (in mM): 243 K^+, 7 Mg^{2+}, 8 $Tris^+$, 34 Cl^-, 175 glutamate, 2 EGTA, 4 ATP, 44 of the anionic form of HEPES, 56 of the neutral form of HEPES, 348 mannitol and 0.5 phenol red. The osmolality was adjusted to ~975 mosm per kg with mannitol or water, and the *p*H to 7.4 with KOH or HEPES. The *p*H 6.0 or 6.5 DF had a similar composition, except that the buffer was 100 mM 2-(*N*-morpholino)ethanesulphonic acid (MES). The 0-Na ASW had the following composition (in mM): 440 *N*-methyl-D-glucammonium ($NMDG^+$), 10 K^+, 11 Ca^{2+}, 44 Mg^{2+}, 55 Cl^-, 5 of the anionic form of *N*-2-hydroxyethylpiperazine-*N*-3-propanesulphonic acid (EPPS), and 5 of the neutral form of EPPS. The *p*H was 8.0 and the osmolality ~975 mosm per kg. In the 50-Na or 440-Na ASW, $NMDG^+$ was replaced with Na^+ on a mole-for-mole basis. 0.5 mM SITS or 1 mM amiloride were added as powders immediately before use. The poly(A)$^+$ RNA was prepared as follows. Fresh rabbit liver was minced in cold phosphate-buffered saline and then the tissue was homogenized in a Waring blender. SDS was added to a final concentration of 0.2%, and the tissue was disrupted in a Dounce homogenizer with the loose-fitting pestle. The volume was increased to about 10 times that of the original tissue by the addition of a solution containing 100 mM NaCl, 10 mM Tris-HCl and 5 mM EDTA (*p*H 7.5). The suspension was extracted three times with water-saturated phenol. The combined interfaces from the phenol extractions were extracted once with 100 mM Tris-HCl (*p*H 9.0) to recover polyadenylated RNA which might have partitioned into the interface. This high-*p*H extract was combined with the original aqueous phase, and the nucleic acids were precipitated overnight after the addition of 0.3 M sodium acetate (*p*H 6.0) and 2.5 vols of ethanol. The precipitate was dissolved in 10 mM Tris-HCl (*p*H 7.5) and the RNA was selectively precipitated at −20 °C overnight with 3 M NaCl. The precipitate was washed three times with 3 M sodium acetate (*p*H 6.0) and once with 90% ethanol, and then dried. The crude RNA was dissolved in distilled water and fractionated by chromatography on oligo(dT)-cellulose, as described previously[18], to isolate the poly(A)$^+$ RNA. The peak fractions from the column were precipitated with ethanol, dried and resuspended either in *p*H 7.4 DF or a solution containing 2 mM EGTA, 100 mM HEPES and 0.5 mM phenol red (*p*H ~7.5, osmolality ~975 mosm per kg). The final concentration of poly(A)$^+$ RNA was 1 μg μl^{-1} in the six experiments similar to that shown here and 0, 0.1 or 0.32 μg μl^{-1} in the 11 additional experiments of the dose-response study.

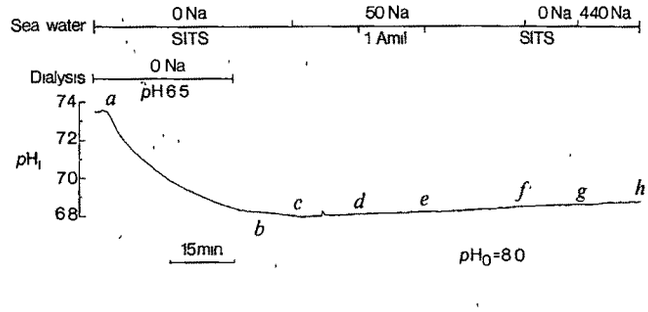

Fig. 2 pH_i recovery in a barnacle muscle fibre injected with fluid pretreated with ribonuclease. See text for details of the experiment. Poly(A)$^+$ RNA was isolated from rabbit liver, as outlined in Fig. 1 legend. We verified that this sample of RNA, when injected into a muscle fibre, caused the expression of a Na–H exchanger. The remainder of the poly(A)$^+$ RNA was incubated with ribonuclease A (200 μg ml^{-1}) at 21 °C for 2 h in a solution buffered to *p*H 8.5 with Tris. The solution was extracted first with phenol and then with chloroform/butanol. Sodium acetate was added to the aqueous phase to a concentration of 0.3 M (*p*H 6). After the addition of 2.5 vols of ethanol, the mixture was incubated for 2 h at −20 °C, and then centrifuged. The precipitate was resuspended at a concentration equivalent to 1 μg of original poly(A)$^+$ RNA per μl.

Na^+ and HCO_3^- for internal Cl^- and H^+. This Na/HCO_3–Cl/H exchanger is functionally quite distinct from mammalian Na–H exchangers[8]. The Na/HCO_3–Cl/H exchanger has an absolute requirement for Na^+, HCO_3^- and Cl^-, is blocked by disulphonic stilbenes such as 4-acetamido-4′-isothiocyanostilbene-2,2′-disulphonate (SITS), and is unaffected by the diuretic amiloride. Na–H exchangers, on the other hand, require Na^+ (but not Cl^- or HCO_3^-), are inhibited by amiloride and are insensitive to SITS.

Figure 1 shows the result of an experiment on a muscle fibre that had been injected with 3 μg poly(A)$^+$ RNA ~18 h previously. An *in vitro* translation assay had previously shown that this RNA sample stimulated protein synthesis. The fibre was pretreated for 23 min by dialysing it with a Na-free fluid at *p*H 7.4. During this time, the fibre was also exposed to a nominally Na^+- and HCO_3^--free ASW containing 0.5 mM SITS. As the barnacle muscle's own pH_i-regulating mechanism requires HCO_3^- and is blocked by SITS[10], our treatment should have prevented any contribution of the barnacle's Na/HCO_3–Cl/H exchanger to pH_i. At point *a* in Fig. 1, when the *p*H of the dialysis fluid was lowered to 6.0, pH_i slowly fell. Dialysis was halted as pH_i reached ~6.75, returning control of pH_i to the fibre (point *b*). In the absence of external Na^+, pH_i drifted slowly upwards (points *b*, *c*). The addition of 50 mM Na^+ to the ASW caused pH_i to increase much more rapidly (points *c*, *d*); this pH_i recovery, which is typical of an active acid-extruding mechanism, was completely blocked by 1 mM amiloride (points *d*, *e*), a known inhibitor of Na–H exchange[17]. Furthermore, removal of amiloride allowed the pH_i recovery to continue (points *e*, *f*). Finally, the removal of external Na^+ blocked further recovery (points *f*, *g*).

The Na-dependent, amiloride-sensitive pH_i recovery observed in this experiment is indicative of Na–H exchange. In 17 similar experiments, we studied expressed Na–H exchanger activity at injected poly(A)$^+$ RNA doses of 0–3 μg per fibre, and fitted the data to the Michaelis–Menten equation using a nonlinear least-squares method. The apparent maximal pH_i recovery rate was 0.66 *p*H units per h, with the half-maximal rate occurring at a dose of 0.6 μg per fibre. In two experiments with the potent amiloride analogue 5′-(*N*-methyl-*N*-isopropyl)-amiloride (not shown), 10 μM of the drug inhibited the Na-dependent pH_i recovery by an average of 71%. Na–H exchanger activity was also found in barnacle muscle fibres injected with 0.95 μg per fibre of poly(A)$^+$ RNA isolated from rat liver. The average pH_i recovery rate in two experiments was 0.40 *p*H units per h, comparable to that observed for fibres injected with the same dose of rabbit RNA. In one such experiment, the recovery was blocked by 1 mM amiloride, and inhibited 74% by 10 μM 5′-(*N*-methyl-*N*-isopropyl)-amiloride.

To determine whether it was the injected mRNA, rather than some other substance, that was responsible for the expression of the Na–H exchanger, we performed six experiments in which the injected material was treated with ribonuclease A in order to degrade the mRNA (see Fig. 2 legend for details). After the muscle fibre had been acid-loaded, the addition of 50 mM Na^+ to the ASW produced little if any increase in pH_i (Fig. 2, points *c*–*f*). Amiloride produced no detectable inhibition (points *d*, *e*). Even the addition of 440 mM Na^+ to the ASW (points *g*, *h*) failed to elicit a sizeable pH_i recovery. In six such experiments, the mean Na-dependent pH_i recovery rate was 0.05 ± 0.08 *p*H units per h, which is not significantly different from zero ($P > 0.35$). Thus, the expression of a Na–H exchanger requires the injection of a ribonuclease-sensitive substance, presumably mRNA.

The RNA we injected is a mixture of mRNA for many different proteins. Until the mRNA responsible for the expression of the Na-H exchanger is isolated, it will be impossible to determine whether the injected RNA caused the expression of a native but previously unexpressed Na-H exchanger, or whether the injected RNA directly encoded a Na-H exchanger. If the latter explanation is correct, this would be the first example of the expression of a mammalian ion exchanger or co-transporter in a foreign system. Our approach for expressing a Na-H exchanger could have important implications for studying the properties and regulation of Na-H exchange, and suggests an approach for cloning the gene(s) for the Na-H exchanger.

We thank Dr Robin Miskimins for performing the *in vitro* translation assay. This work was supported by NIH grants CA06519 (W.C.S.), NS18400 (W.F.B.), AM17433 (W.F.B.), and AM01022 (W.F.B.).

Structural organization of the *bcr* gene and its role in the Ph′ translocation

Nora Heisterkamp, Kees Stam & John Groffen

Oncogene Science, Inc., 222 Station Plaza North, Mineola, New York 11501, USA

Annelies de Klein & Gerard Grosveld

Department of Cell Biology and Genetics, Erasmus University, 3000 DR Rotterdam, The Netherlands

The Philadelphia (Ph′) chromosome, an abnormal chromosome 22 (ref. 1), is one of the best-known examples of a specific human chromosomal abnormality strongly associated with one form of human leukaemia, chronic myelocytic leukaemia (CML). The finding[2] that a small region of chromosome 9 which includes the c-*abl* oncogene is translocated to chromosome 22 prompted studies to elucidate the molecular mechanisms involved in this disease. We have demonstrated previously that the chromosome 9 of one patient with CML contains a breakpoint 14 kilobases (kb) 5′ of the most 5′ v-*abl*-homologous exon[3]. These data suggest a role for c-*abl* in CML, a theory supported by the presence of an abnormally sized *abl* messenger RNA[4,5] and protein[6] in the CML cell line K562. The region involved in the translocation on chromosome 22 has also been identified: all Ph′-positive patients examined to date have a breakpoint within a 5.8-kb region, for which we have proposed the name 'breakpoint cluster region' (*bcr*)[7]. To determine whether *bcr* contains protein-encoding regions, probes from *bcr* were tested for their ability to hybridize to complementary DNA sequences. A 0.6-kb *Hin*dIII/*Bam*HI *bcr* restriction enzyme fragment proved suitable for isolating several cDNA clones from a human fibroblast cDNA library[8]. Using *bcr* cDNA sequences, we obtained data strongly suggesting the presence of a chimaeric *bcr/abl* mRNA in the leukaemic cells of Ph′-positive CML patients. The recent isolation of cDNA clones containing *bcr* and *abl* sequences confirms this finding[12]. Because the *bcr* part of the chimaeric mRNA could be required to induce the transforming activity of the human c-*abl* oncogene, we have now initiated studies to characterize the normal '*bcr* gene' and to determine the effect of a translocation within its coding domain. We demonstrate that as a result of the Ph′ translocation, a variable number of *bcr* exons are included in the chimaeric *bcr/abl* mRNA. The *bcr* gene sequences in this mRNA could be responsible for the transition of the *abl* cellular proto-oncogene into an oncogene.

The largest cDNA, V1-3, containing an insert of 2.2 kb, was characterized in detail by restriction enzyme mapping (Fig. 1*a*) and sequence analysis (Fig. 1*b*). The cDNA contains one long open reading frame, starting at the poly(G) tail at the 5′ end and continuing to nucleotide 1,770, where a stop codon is encountered. All other reading frames have many stop codons within the entire region. The long open reading frame has the coding capacity for 589 amino-acid residues, corresponding to a protein of relative molecular mass (M_r) ~65,000; at the 3′ end, a polyadenylation signal occurs at nucleotide 2,182 followed by a poly(A) tail beginning at base 2,208 indicating that the cDNA contains the complete 3′ end of the gene. Although translational start sequences are encountered at the 5′ end, it is unlikely that this cDNA contains a complete copy of the mRNA, as Northern blot hybridizations indicate the presence of *bcr* mRNAs of ~4.0 and ~6.5 kb. Computer searches of newly isolated protein sequences derived directly from proteins or deduced from cDNA nucleotide sequences frequently result in the identification of proteins with partial homology. Such information is valuable, frequently allowing the assignment of a preliminary function to an unknown protein. Therefore, the PIR FASTP program[10] was used to search for *bcr*-homologous proteins; no proteins with significant homology were found, indicating that the *bcr* protein exhibits an as yet unidentified cellular function.

To determine the orientation of the *bcr* gene on chromosome 22, 5′ and 3′ probes were prepared from the V1-3 cDNA and hybridized to cosmids[7] containing human chromosome 22 sequences. This established that the 5′ end of the *bcr* gene is towards the centromere of chromosome 22 and is retained after the Ph′ translocation; the 3′ end of the *bcr* gene lies in the direction of the telomere and is translocated to chromosome 9 in the t(9; 22) translocation. The cDNA hybridizes to restriction enzyme fragments distributed over a region of up to 45 kb of chromosome 22 DNA (Fig. 2*a*). Within this region, a minimum of 13 exons are present. To determine the exact position and number of exons within the breakpoint cluster region, all hybridizing regions in *bcr* were sequenced and compared with the V1-3 cDNA. Four relatively small exons, designated 1-4, were present within *bcr*, varying in size from 76 to 105 base pairs (bp) (Fig. 2*b*); in the cDNA, these exons correspond to nucleotides 483-836 (Fig. 1*b*). As *bcr* was defined as the area on chromosome 22 in which the Ph′ breakpoints are found, we conclude that the breakpoints occur within a gene.

Having determined the position of the exons within *bcr*, we investigated whether the breakpoints occur in exon or intron regions. For CML DNA such as that of CML patient C481, this was readily determined. We had previously demonstrated[7] a breakpoint within a 1.2-kb H/Bg *bcr* fragment in several CML DNA samples, including that of patient C481. As no coding sequences are located within this region (see Fig. 2), patients such as C481 must have a chromosomal breakpoint in the intron between the exons designated 3 and 4.

A less simple situation was encountered in the DNA of patients 0311068 and 7701C. Nonetheless, cloning of $9q^+$ breakpoint fragments from these DNAs (data not shown) and restriction enzyme analysis followed by Southern hybridization enabled us to locate the breakpoints between exons 2 and 3 (see Fig. 2) The breakpoints in the previously cloned[3,7] $9q^+$ breakpoint fragments of patients 0319129 and 02120185 were analysed by DNA sequencing. In addition, we cloned the $22q^-$ breakpoint

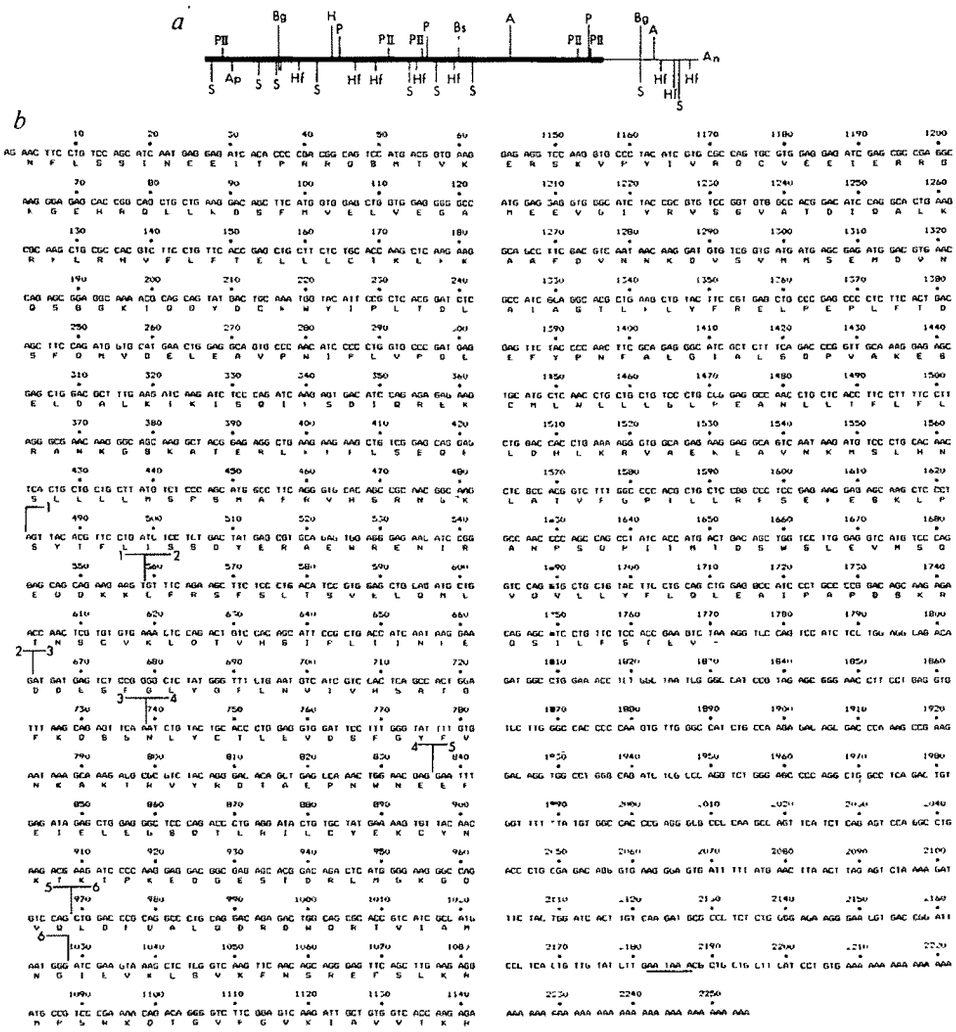

Fig. 1 *bcr* cDNA V1-3 *a*, Restriction enzyme map of V1-3 The black bar indicates the open reading frame sequences, the thin line non-translated sequences. The 3′ end of the cDNA containing the poly(A) tail is depicted as A_n. Restriction enzymes include A, *Ava*I; Ap, *Apa*I, B, *Bgl*II; Bs, *Bst*EII; H, *Hin*dIII, Hf, *Hin*fI; P, *Pst*I, PII, *Pvu*II, S, *Sau*3A. *b*, DNA sequence and translation of V1-3 sequence. Amino-acid residues are indicated with a one-letter symbol below the sequence The exact position of exons designated 1–6 (see Fig 2*a*) within V1-3 *bcr* cDNA is shown by the numbers above the sequence. DNA sequencing was performed using the dideoxy-chain termination method[14] on restriction enzyme fragments of the cDNA subcloned into M13 phage[15]. All regions were sequenced on both strands.

fragments of patient 0319129 (unpublished results) and of the cell line K562. DNA sequence analysis of the breakpoint regions of these fragments and that of the sequence of the corresponding chromosome 22 regions enabled us to define the point of translocation for these DNAs (see Fig. 2). None of the breakpoints analysed here could be located within an exon, indicating that in the Ph′ translocation, breakpoints occur within intron regions of *bcr*. For four of the six DNA samples analysed, the translocation would result in the transcription of a mRNA that includes *bcr* exons 1 and 2 (see Fig. 2), in two CML DNAs the third exon would be additionally incorporated in the chimaeric *bcr*/c-*abl* mRNA. Exon 3 encodes only 25 amino acids, not substantially increasing the size of the chimaeric protein.

A knowledge of the DNA sequence of the translocation junction point may provide additional information about the mechanism of chromosomal translocation. Figure 3*a* shows the sequence of the region containing the crossover point for translocation in the DNA of patient 0319129 and compares this with normal chromosome 22 and 9 DNA sequences. In 0319129 DNA, the chromosomal break has occurred in a rather 'precise' manner, leading to the generation of a $22q^-$ and $9q^+$ sequence exactly reflecting the sequence of the normal chromosome 22 and 9 DNA sequences. However, at the breakpoint, a C nucleotide is found in both the $9q^+$ and $22q^-$ sequences, whereas the chromosome 22 sequence contains a G at that position. Note that both chromosomes 9 and 22 contain limited stretches of homology near the break (Fig. 3*a* underlined); a DNA search revealed homology of this region to human *Alu* repetitive sequences.

No such similar stretches of homologous sequences between chromosomes 9 and 22 occur at the breakpoint in the DNA of patient 0212015 (Fig. 3*b*) or in that of K562 DNA (data not shown). In the $9q^+$ DNA of patient 0212015, sequences are found between the breakpoints on chromosomes 9 and 22 (Fig. 3*b*) which are not present in the sequenced region of the normal chromosomes 9 and 22. This suggests that in the $9q^+$ chromosome a secondary event has taken place; it is possible that after translocation of chromosome 22 sequences to chromosome 9, a deletion affecting chromosome 9 sequences occurred. The arrow indicating the breakpoint on chromosome 9 (see Fig. 3*b*) would then represent the point of deletion. In addition, compared with the normal chromosome 9 sequences, the chromosome 9 sequences of the $9q^+$ fragment contain 13 nucleotide changes within an 81-bp stretch. These changes may reflect differences between individuals (the control chromosome 9 sequences were isolated from a human lung carcinoma cosmid library); however, the number of nucleotide substitutions would be very high in such an event. Moreover, the chromosome 22 part of the $9q^+$ fragment contains no nucleotide changes in either intron or exon sequences, favouring the explanation of inefficient DNA repair on deletion of chromosome 9 sequences.

These results indicate that *bcr* is part of a gene oriented with its 5′ end towards the centromere of chromosome 22. In the Philadelphia translocation, a break occurs within *bcr*, and sequences from chromosome 9 which contain the human c-*abl* oncogene in all Ph′-positive cases examined[7,9] are translocated to the 3′ of the truncated *bcr* gene. The joining of *bcr* and c-*abl* sequences is highly specific for CML, as this configuration has been found in complex translocations[9] and even in the leukaemic cells of one CML patient cytogenetically lacking the Ph′ chromosome[11]. Because the orientation of c-*abl* on chromosome 9 is also centromere–5′–3′–telomere, *bcr* and c-*abl* are joined in a

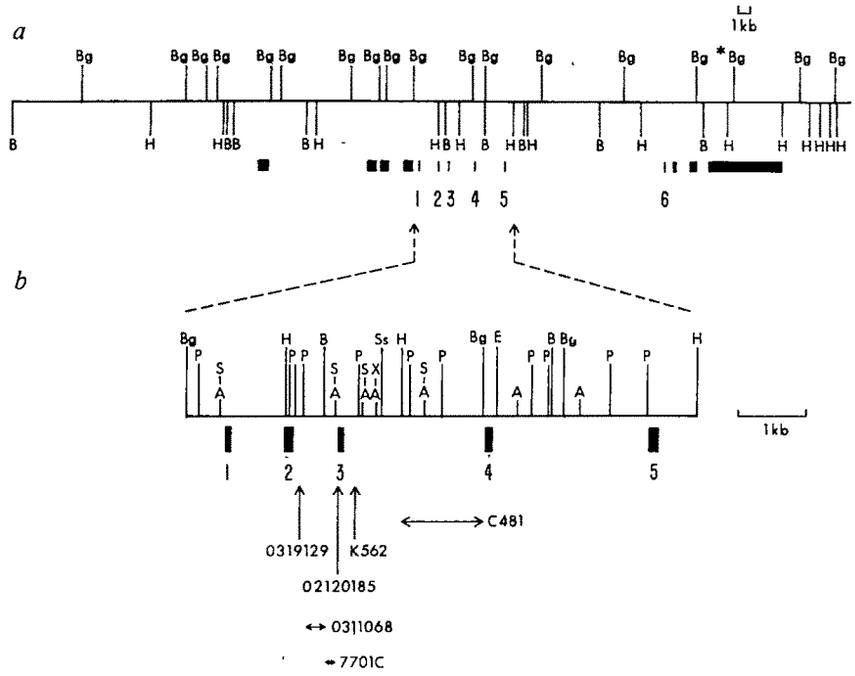

Fig. 2 Genomic organization of the *bcr* gene. *a*, Restriction enzyme map of chromosome 22 sequences encompassing *bcr*. Exons are indicated by black boxes below the restriction enzyme map. The position of the numbered exons has been determined by sequencing; all other exons were located by hybridization to the V1-3 cDNA. The asterisk indicates a polymorphic *Bgl*II restriction enzyme site. *b*, Restriction enzyme map of the breakpoint cluster region, with the exons as indicated in *a*. Below the map, the approximate positions of the breakpoints in different CML DNAs are indicated by horizontal or vertical arrows. Restriction enzymes include: A, *Ava*I; B, *Bam*HI; Bg, *Bgl*II; E, *Eco*RI, H, *Hin*dIII; P, *Pst*I; S, *Sma*I, Ss, *Sst*I, X, *Xho*I. The breakpoint of the 22q$^-$ chromosome from DNA 0319129 was cloned as a 9.5-kb *Bgl*II fragment in Charon 30 according to previously described methods[16]. 9q$^+$ fragments were isolated by cloning a 7.2-kb *Bam*HI fragment and a 7.7-kb *Eco*RI fragment into Charon 30 and λgtwes, respectively.

head-to-tail fashion on the Ph′ chromosome. Although the distance between the most 5′ v-*abl* homologous to v-*abl* and the physical breakpoint may vary from 14 kb (patient 0319129) to >100 kb (K562), the effect of the translocation on the expression of the *bcr* gene and c-*abl* seems to be very similar in different patients: in K562 and in Ph′-positive CML patients, abnormal RNA transcripts of ~8.5 kb are detected, which hybridize to both c-*abl* and 5′ *bcr* exon probes. The molecular cloning of a chimaeric cDNA from K562 cells has provided definitive proof for the existence of chimaeric mRNA[12]. The chimaeric mRNAs must be the result of transcription initiating at the promoter of the *bcr* gene; depending on the exact location of the breakpoint, the transcript will include all 5′ exons in addition to either exons 1 and 2 or exons 1, 2 and 3 of *bcr*. Recent sequence analysis of K562 *bcr*/*abl* cDNA confirms the variable presence of the third exon. In K562 we found that, as predicted, the third exon is present in the cDNA, immediately preceding c-*abl* sequences. In contrast, Southern blot analysis of the molecularly cloned 22q$^-$ genomic DNA fragment of, for example, patient 0319129 unambiguously demonstrates that in this patient exon 3 has been removed from the Ph′ chromosome and will not be included in a chimaeric *bcr*/*abl* transcript. Transcription continues into the c-*abl* oncogene, including, as a minimum, the most 5′ v-*abl*-homologous exon and all exons 3′ of it, including the phosphotyrosine acceptor site[13]. We do not know whether the inclusion of exon 3 in the chimaeric mRNA has an effect on the progression of the disease.

Chromosomal aberrations may be generated by specific events involving recombination-prone DNA sequences. Alternatively, such recombination events could occur almost at random. In either case, a very limited number of translocations will result in gene alterations leading to the disruption of normal growth and differentiation. In the Ph′ translocation, we have found that breakpoints on chromosome 9 are spread over a region of up to 100 kb. The breakpoints on chomosome 22 occur within a smaller region of around 50 kb. Nonetheless, no sequence homology can be found between breakpoint regions of different CML patients or coding regions of c-*abl* and *bcr* genes. Therefore, we may conclude that the processes underlying the Ph′ translocation are random recombination events. Once such recombinations result in a genomic configuration that allows the transcription of chimaeric *bcr*/*abl* mRNA, malignant proliferation of specific cell types may occur. It seems highly likely that this chimaeric mRNA is translated into protein because an

Fig. 3 Breakpoint sequences of the DNAs of two CML patients. *a*, Sequence of 0319129 DNA; the sequences are in a 5′–3′ orientation. Normal chromosome 9 sequences (first line) are from non-CML DNA, the 9q$^+$ and 22q$^-$ sequences (second and third lines) are from DNA of patient 0319129. Normal chromosome 22 sequences (fourth line) are from non-CML DNA An arrow indicates the breakpoint on chromosomes 9 and 22; the nucleotide C found in both the 9q$^+$ and 22q$^-$ sequences at the breakpoint is boxed Limited regions of homology between the normal chromosome 9 and 22 sequences are underlined *b*, Breakpoint sequence of 02120185 DNA; normal chromosome 9 and 22 sequences (first and third lines in each set) were from non-CML DNA The 9q$^+$ sequence on the second line contains an area boxed to indicate that it does not originate from the normal chromosomes 9 or 22 sequenced in the present experiments. Dots above the chromosome 9 sequences indicate nucleotide differences at those positions from the 9q$^+$ chromosome. The beginning of exon 3 (see Fig 2*b*) in the 9q$^+$ and 22 sequence is indicated in the figure Small restriction enzyme fragments containing the breakpoints were chosen for sequence analysis, based on restriction enzyme mapping data and comparison with normal chromosome 9 and 22 maps.

abnormally sized 210,000-M_r c-*abl* protein was detected in K562 cells. In contrast to the normal c-*abl* protein, the P210 has tyrosine kinase activity[6].

It is tempting to speculate that the *bcr* moiety of the fusion protein is responsible for this effect. However, although the consequences of the Ph' translocation on a molecular level are becoming evident, it remains to be established whether this phenomenon is actually the cause or merely one of the steps that eventually result in CML.

We thank Pamela Hansen and Gail Blennerhassett for technical assistance, John Stephenson for critical reading of the manuscript, H. Okayama for the generous gift of the cDNA library and Rosanne Beyer for typing the manuscript. This work was supported by Oncogene Science, Inc.

The nicotinic acetylcholine receptor (AChR) from fish electric organ has a subunit structure of $\alpha_2\beta\gamma\delta$, and this is thought to be also the case for the mammalian skeletal muscle AChR[1–3]. By cloning and sequencing the complementary or genomic DNAs, we have previously elucidated the primary structures of all four subunits of the *Torpedo californica* electroplax[4–6] and calf muscle AChR[7–10] and of the α- and γ-subunits of the human muscle AChR[7,11]; the primary structures of the γ-subunit of the *T. californica* AChR[12] and the α-subunit of the *Torpedo marmorata* AChR[13,14] have also been deduced elsewhere. We have now cloned DNA complementary to the calf muscle messenger RNA encoding a novel polypeptide (the ε-subunit) whose deduced amino-acid sequence has features characteristic of the AChR subunits and which shows higher sequence homology with the γ-subunit than with the other subunits. cDNA expression studies indicate that the calf ε-subunit, as well as the calf γ-subunit, can replace the *Torpedo* γ-subunit to form the functional receptor in combination with the *Torpedo* α-, β- and δ-subunits.

The initial cDNA clone for the calf ε-subunit was isolated by cross-hybridization with a calf γ-subunit cDNA probe in an experiment aimed at cloning an upstream cDNA sequence for the calf γ-subunit by primer extension (see Fig. 1 legend). Figure 1 shows the nucleotide sequence of the mRNA encoding the calf ε-subunit precursor, deduced from the cDNA sequence, together with the predicted primary structure of the polypeptide. We deduce that the ε-subunit precursor consists of 491 amino acids including a hydrophobic prepeptide[15] of 20 amino acids, and calculate the relative molecular masses of the ε-subunit and its precursor to be 52,568 and 54,562, respectively.

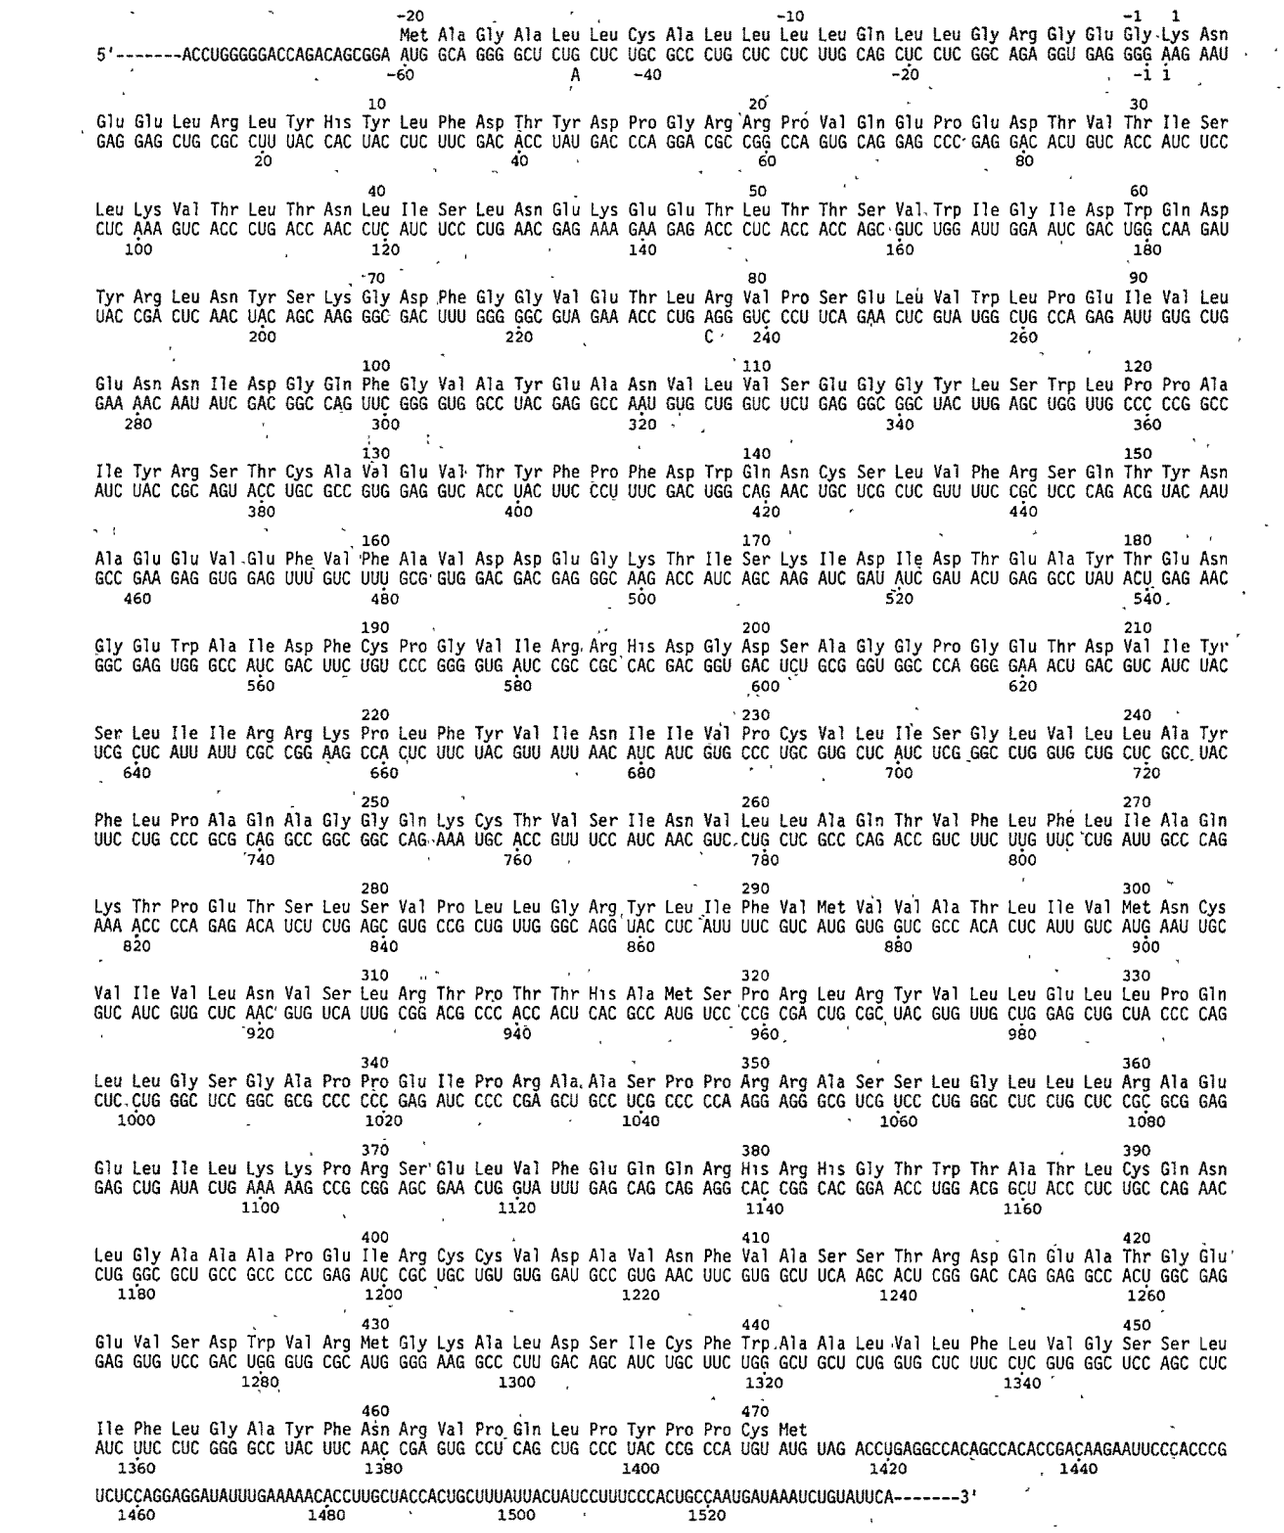

Figure 2 shows the alignment of the amino-acid sequences of the calf ε-subunit precursor and the calf, human and *T. californica* γ-subunit precursors. The mature calf ε-subunit shows 53, 53 and 57% sequence homology with the mature calf, human and *Torpedo* γ-subunits, respectively, whereas the degrees of its homology with other mature AChR subunits are as follows: calf, human and *Torpedo* α-subunit, 30% (refs 4, 7), calf β-subunit, 37% (ref. 8), *Torpedo* β-subunit, 39% (ref. 5), calf δ-subunit, 45% (ref. 10) and *Torpedo* δ-subunit, 44% (ref. 5). Homology among the mature γ-subunits is 92%, 56% and 55%, respectively, for the calf/man, calf/*Torpedo* and man/*Torpedo* pairs. Because the calf ε-subunit shows similar degrees of homology with the calf, human and *Torpedo* γ-subunits, the divergence of the ε- and γ-subunits may have occurred around the time of separation of mammals and fish. Thus, it is possible that fish have a second, undetected gene encoding a γ/ε-family subunit, which may or may not now be active.

The calf ε-subunit shares structural features common to all four subunits of the fish and mammalian AChR[4–12,14]. It contains four strongly hydrophobic segments[4–12,14] (M1–M4) and an amphipathic segment[16–18] (MA). Our expression studies using site-directed mutagenesis of the α-subunit cDNA indicate that these five putative α-helical transmembrane segments are all required for the operation of the ionic channel[18]. The hydrophilicity profile[19] and the predicted secondary structures[20] of the calf ε-subunit are also similar to those of the other AChR subunits[4–12,21]. These findings suggest that the ε-subunit is oriented across the membrane in the same manner as the four other subunits. Three cysteine residues (aligned at positions 128, 142 and 231) and one potential *N*-glycosylation site[22] (aligned at position 141) are conserved in all AChR subunits whose sequences are known[4–14]. The calf ε-subunit contains two additional potential *N*-glycosylation sites (aligned at positions 66 and 307), one of which (position 66) is assigned to the extracellular side of the membrane[4–12,14]. Because our expression studies are consistent with the presence of a disulphide bridge between the conserved cysteine residues 128 and 142 of the α-subunit[18], the corresponding cysteine residues of the ε-subunit may also form a disulphide bond.

To examine whether the ε-subunit can function as an AChR subunit, we synthesized the mRNA specific for this subunit (or the γ-subunit) *in vitro*[23,24] using the cDNA template and injected the mRNA, combined with the *Torpedo* α-, β- and δ-subunit-specific mRNAs synthesized similarly[18], into *Xenopus* oocytes. The oocytes were then tested for response to acetylcholine (ACh) applied ionophoretically by recording the intracellular potentials. All of the 61 oocytes injected with the calf ε-subunit and the three *Torpedo* mRNAs and 38 of the 56 oocytes injected with the calf γ-subunit and the three *Torpedo* mRNAs responded to ACh (Fig. 3) with mean ACh sensitivities (for the responsive oocytes) of 510 and 8 mV μC^{-1}, respectively. None of 60 control oocytes injected only with the *Torpedo* α-, β- and δ-subunit-specific mRNAs was responsive ($<\sim 0.2$ mV μC^{-1}). The mean ACh sensitivity of 70 responsive oocytes out of 72 oocytes injected with the *Torpedo* α-, β-, γ- and δ-subunit-specific mRNAs[18] was 1,300 mV μC^{-1}. The atropine-resistant and (+)tubocurarine-sensitive nature of the observed ACh responses (Fig. 3) indicates the formation of the nicotinic AChR. These results show that the calf ε-subunit, as well as the calf γ-subunit, can be functionally substituted for the *Torpedo* γ-subunit.

Blot hybridization analysis using ε-subunit cDNA probe of poly(A)$^+$ RNA from the skeletal muscle of a 4-month-old fetal calf revealed a hybridization-positive species with an estimated size of ~4,200 nucleotides (Fig. 4*A*, lane *a*). No hybridizable species was detected, however, in poly(A)$^+$ RNA from the skeletal muscle of a 7-month-old fetal calf (Fig. 4*A*, lane *b*), a 9-month-old fetal calf or a newborn calf or from adult bovine diaphragm (data not shown).

Figure 1

The AChR is present predominantly at the neuromuscular junction in adult muscle, whereas in embryonic muscle and denervated adult muscle the AChR also occurs in the extrajunctional membrane[1,2]. Some reports suggest that the two types of AChR are structurally different, the junctional AChR being slightly more acidic than the extrajunctional AChR[25]. Our amino-acid sequence data reveal that the calf ε-subunit contains more acidic residues and less basic residues than does the calf γ-subunit[9]; the numbers of charged residues contained in the mature ε- and γ-subunits are 20/18 Asp, 33/28 Glu, 26/31 Arg, 12/14 Lys and 5/11 His, respectively. However, the content of both the γ- and ε-subunit mRNAs in fetal calf muscle, like that of the β-subunit mRNA[8], decreases with increasing age of the calf (Fig. 4), although the relative contents of the ε- and γ-subunit mRNAs in other age groups were not studied systematically. Muscle contains much smaller amounts of ε-subunit mRNA than of γ-subunit mRNA (Fig. 4), and the latter is present in similar amounts to the α-, β- and δ-subunit mRNAs[7–10]. It thus remains uncertain whether the differential presence of the γ- and ε-subunits is responsible for the difference in the junctional and extrajunctional forms of the AChR. Alternatively, the ε-subunit (or the γ-subunit) may be a

Fig. 1 (opposite) Primary structure of the mRNA encoding the ε-subunit precursor of the calf muscle AChR. The nucleotide sequence of the mRNA was deduced by sequence analysis[28] of the cDNA inserts in clones pcACRε64, pcACRε1 and pcACRε2. Nucleotide residues are numbered in the 5′ to 3′ direction, beginning with the first residue of the codon specifying the amino-terminal residue of the mature ε-subunit, and the nucleotides on the 5′ side of residue 1 are indicated by negative numbers. Because the 3′-untranslated sequence presented contains no polyadenylation signal[29] and is not followed by a poly(A) tract, this sequence is incomplete, as is the 5′-untranslated sequence shown. The amino-acid sequence, deduced by using the reading frame of the mRNA corresponding to the known amino-acid sequences of the AChR subunit precursors[4–14], is shown above the nucleotide sequence. Amino-acid residues are numbered beginning with the amino-terminal residue of the mature ε-subunit, and the preceding residues are indicated by negative numbers. The possibility that the initiating methionine is located upstream of the 5′ end of the cDNA sequence shown cannot be excluded. The nucleotide differences observed between the individual clones are as follows: G (pcACRε64) or A (pcACRε2) at position −46; A (pcACRε64) or C (pcACRε1) at position 235; the G at position 279 and the C at position 285 of pcACRε1 (instead of A and T, respectively, in pcACRε64), derived apparently from the synthetic primer, are not shown. **Methods.** Total RNA was extracted from newborn or fetal calf skeletal muscle, and poly(A)$^+$ RNA was isolated by oligo(dT)-cellulose chromatography. The oligodeoxyribonucleotide 5′-GTTGTTCTCCAGCAC-3′, complementary to residues 271–285 of the calf γ-subunit mRNA[9], was synthesized by the triester method and used for specific priming of reverse transcription. Single-stranded cDNA was synthesized using 5 μg of this primer and 100 μg of newborn calf muscle poly(A)$^+$ RNA as template and was converted to double-stranded cDNA, which was cloned in pBR322 plasmid by inserting it into the *Pst*I site using poly(dG)·poly(dC) homopolymeric extensions. *Escherichia coli* χ1776 or HB101 was used for transformation, and $\sim 3 \times 10^5$ tetracycline-resistant transformants were screened by hybridization at 60 °C with the *Hin*cII(88)/*Ava*II(202) fragment excised from clone pcACRγ5 (ref. 9) to yield one positive clone (pcACRε1 carrying nucleotides 84–285); the restriction endonuclease sites are identified by numbers indicating the 5′-terminal nucleotide generated by cleavage; all hybridization probes were labelled by nick-translation with [α-^{32}P]dCTP. Another batch of cDNA clones prepared similarly ($\sim 1.5 \times 10^5$ transformants) was then screened by hybridization at 60 °C with the *Mbo*II(152)/*Fnu*4HI(260) fragment from clone pcACRε1 to give one positive clone (pcACRε2 carrying nucleotides −46 to 203). The procedures used for the above experiments have been described previously[30]. A cDNA library was next constructed by the procedure of Gubler and Hoffman[31], using 10 μg of oligo(dT)$_{12-18}$ primer and 13 μg of a fraction of fetal (4-month-old) calf muscle poly(A)$^+$ RNA (>~4,000 nucleotides; see Fig. 4) obtained by centrifugation in a gradient of 5–25% (w/v) sucrose[32]. Screening of $\sim 8 \times 10^5$ tetracycline-resistant transformants by hybridization at 60 °C with the *Hin*fI(−46)/*Hin*fI(171) fragment from clone pcACRε2 yielded one positive clone (pcACRε64 carrying nucleotides −82 to 1,539); the *Hin*fI(−46) site was generated in pcACRε2 at the junction of the 5′ end of the cDNA insert and the poly(dG)·poly(dC) tail.

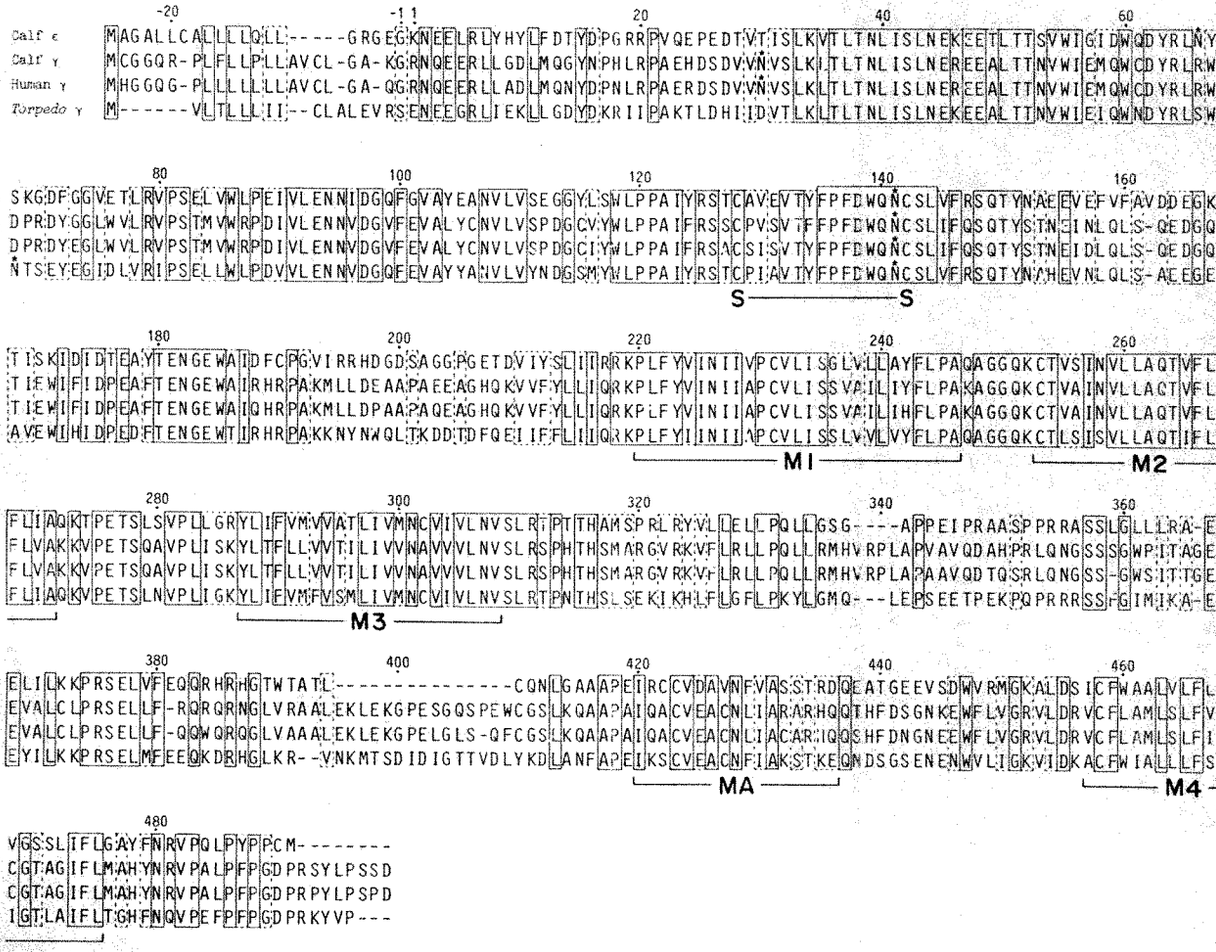

Fig. 2 Alignment of the amino-acid sequences of the calf AChR ε-subunit precursor (top) and the calf (second row), human (third row) and *T. californica* AChRγ-subunit precursors (bottom). The one-letter amino-acid notation is used. The sequence data for the calf, human and *T. californica* γ-subunit precursors have been taken from refs 9, 11 and 6, respectively. Sets of four identical residues at one aligned position are enclosed by solid lines, and sets of four identical or conservative residues at one aligned position by dashed lines. Conservative amino-acid substitutions are defined as pairs of residues belonging to one of the following groups: S, T, P, A and G; N, D, E and Q; H, R and K; M, I, L and V; F, Y and W. Gaps (-) have been inserted to achieve maximum homology. The degrees of homology given in the text were calculated on the basis of the alignment of the amino-acid sequences of the 11 AChR subunits (calf, human and *Torpedo* α, calf and *Torpedo* β, calf, human and *Torpedo* γ, calf and *Torpedo* δ and calf ε), gaps being counted as one substitution regardless of their length. The positions in the aligned sequences including gaps are numbered beginning with the amino-terminal residue of the mature subunits, and the preceding positions are indicated by negative numbers. The asparagine residues as potential glycosylation sites are marked with asterisks; only those preceding segment M1 are shown. The putative disulphide bridge (S—S) and the putative transmembrane segments (M1, M2, M3, M4 and MA) are indicated; segment MA has been assigned by comparison with that of the *Torpedo* α-subunit defined by deletion mapping[18].

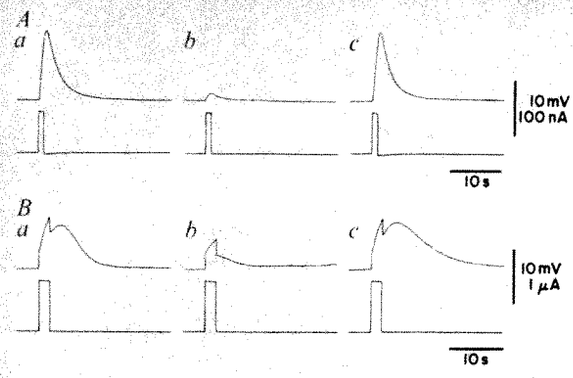

Fig. 3 ACh potentials recorded from *Xenopus* oocytes injected with mRNA specific for the calf AChR ε-subunit (*A*) or γ-subunit (*B*) together with the *T. californica* AChR α-, β- and δ-subunit-specific mRNAs. The recordings were made at room temperature in Ringer's solution containing 1 μM atropine and 5 mM $MgCl_2$ instead of $CaCl_2$: upper traces, ACh potentials; lower traces, currents used for ionophoresis of ACh (backing current, 12 nA). The membrane potential was held at −70 mV. Responses to ACh were recorded before (*a*) and 6–8 min after perfusion with 2 μM (+)tubocurarine (*b*) and 8–9 min after washing out the antagonist (*c*).

Methods. The 320-base-pair (bp) fragment extending from the *Ava*II site generated at the 5′ end of the cDNA insert to the *Ava*II(238) site and the *Ava*II(238)/*Eco*RI (1,444) fragment, derived from clone pcACRε64, and the ~520-bp fragment of clone pACRγ14 (ref. 6) extending from the *Eco*RI(1,474) site to the *Pvu*II site on the vector DNA were ligated. The resulting ~2.0-kilobase-pair (kb) fragment was isolated, treated with *E. coli* DNA polymerase I (Klenow fragment) in the presence of dGTP, dCTP and dTTP and inserted into the *Sma*I site of the plasmid pSP64 (ref. 24) in the same orientation as the SP6 promoter to yield the plasmid pSPcε. The *Pst*I(−100)/*Xho*I(207) fragment from clone pcACRγ11 (ref. 9), the *Xho*I(207)/*Hin*dIII(1,181) fragment, the *Hin*dIII(1,181)/ *Acc*I(1,560) fragment and the ~180-bp fragment extending from the *Acc*I(1,560) site to the *Pvu*II site on the vector DNA, derived from clone pcACRγ5 (ref. 9), and the ~3.0-kb *Sma*I/*Pst*I fragment from pSP64 were ligated. The resulting plasmid pSPcγ, carrying the entire calf γ-subunit cDNA (except for a portion of the 5′-noncoding region) in the same orientation as the SP6 promoter, was identified by colony hybridization with both the above *Xho*I/*Hin*dIII and *Hin*dIII/*Acc*I fragments as probes and by restriction endonuclease analysis. The calf AChR ε- and γ-subunit-specific mRNAs were synthesized *in vitro*, using *Sac*I-cleaved pSPcε and *Eco*RI-cleaved pSPcγ, respectively, as templates and were then capped *in vitro* with vaccinia virus mRNA guanylyl transferase[23]. Each of these mRNAs, combined with the *T. californica* AChR α-, β- and δ-subunit-specific mRNAs[18] (molar ratio of the α-, β-, γ/ε- *and* δ-subunit-specific mRNAs, 2:1:2:1; total mRNA concentration, 120–340 ng μl^{-1}), was injected into *Xenopus laevis* oocytes (average volume injected per oocyte, ~20 nl). The oocytes were incubated for 3 days in conditions described previously[33] before being tested for response to ACh.

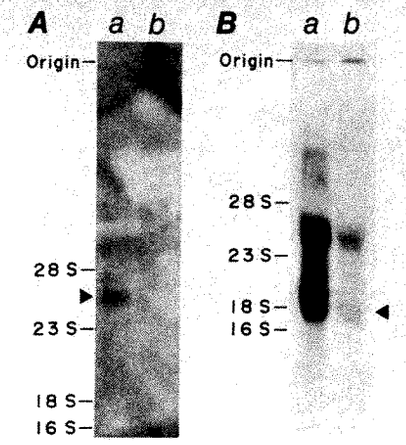

Fig. 4 Autoradiogram of blot hybridization analysis of calf muscle RNA with an AChR ε-subunit (*A*) or γ-subunit (*B*) cDNA probe. Samples of skeletal muscle poly(A)$^+$ RNA (40 μg each in *A* or 30 μg each in *B*) from a 4-month-old (lane *a*) or a 7-month-old (lane *b*) fetal calf were denatured with 1 M glyoxal and 50% dimethyl sulphoxide, electrophoresed on 1.5% agarose gels and transferred to a nitrocellulose filter[34] (*A*) or diazophenylthioether paper[35] (*B*). The hybridization probe used was the 1,535-bp fragment of clone pcACRε64 extending from the *Pst*I site flanking the 5′ end of the cDNA insert to the *Eco*RI(1,444) site (*A*) or an equimolar mixture of the 1,004-bp fragment extending from the *Pst*I site flanking the 5′ end of the cDNA insert to the *Acc*I(1,054) site and the *Acc*I(1,054)/*Acc*I(1,560) fragment, derived from clone pcACRγ5 (ref. 9) (*B*); the two probes, labelled by nick-translation with [α-^{32}P] dCTP, had nearly equal specific radioactivities (~4 × 10^8 c.p.m. per μg), but the photograph in *A* is more exposed than that in *B*, to intensify the hybridization signal. The size markers used were calf and *E. coli* ribosomal RNA. The positions of the ε-subunit mRNA (~4,200 nucleotides) (*A*) and the γ-subunit mRNA (~2,000 nucleotides[9]) (*B*) are indicated by arrowheads; the larger RNA species (~3,700 nucleotides) hybridizable with the γ-subunit cDNA probe probably represents incompletely spliced RNA as described previously[9].

component of a third type of AChR which appears at a particular stage of muscle development[26]. It is also possible that the ε-subunit (or the γ-subunit) is a constituent of the nicotinic AChR present in neuronal synapses[27].

Conti-Tronconi *et al.*[3] have determined the sequences of the amino-terminal 23–35 amino-acid residues of the four polypeptides derived from fetal calf muscle AChR. Three of these sequences agree reasonably well with the amino-terminal sequences of the mature α- (ref. 7), β- (ref. 8) and δ-subunits[10] deduced by us from the cDNA sequences, but the fourth sequence (designated x) matches neither the γ-subunit[9] nor the ε-subunit. This may imply the possible existence of still another subunit of the AChR.

We thank Dr Takashi Miyata for computer analysis and helpful discussions. This investigation was supported in part by research grants from the Ministry of Education, Science and Culture of Japan, the Mitsubishi Foundation and the Japanese Foundation of Metabolism and Diseases.

The antigen receptor on T lymphocytes has recently been characterized as a heterodimeric, transmembrane glycoprotein consisting of disulphide-linked α (acidic) and β (basic) subunits of relative molecular mass (M_r) 40,000–45,000 each. The genes encoding these proteins have been cloned[1–4] and shown to resemble immunoglobulin genes in both overall structure and the requirement for DNA rearrangement before expression[5–11]. In humans, three additional proteins, termed the T3 complex, are found associated with the clonotypic receptor, and a role for T3 in receptor expression has been proposed[12–15]. Despite these recent advances in characterizing the antigen receptor complex, there is as yet little understanding of T-cell maturation, particularly the stage of T-cell ontogeny at which the genes encoding the antigen receptor and its associated structures are expressed and assembled. In the adult, stem cells destined to differentiate into T cells arise in the bone marrow and migrate to the thymus[16], where T-cell precursors proliferate, develop a preference for recognizing antigens in the context of self MHC molecules[17,18] and are released to the periphery. Recently, cells that have the properties of immature murine thymocytes have been isolated and described[19,20]. We have now analysed these cells with a series of molecular probes and we describe three distinct patterns of T-cell antigen receptor gene rearrangements in developing thymocytes.

Two-colour flow cytometric analysis of the Lyt2 and L3T4 T-cell-surface antigens on adult murine thymocytes and analysis of T8 and T4 markers on human thymocytes using monoclonal antibody plus complement-mediated lysis reveal four major subpopulations[19–22] (Fig. 1). In the mouse, cells bearing both Lyt2 and L3T4 make up most thymocytes (80–85%) and correspond to cells found predominantly in the cortex. Immunocompetent, mature thymocytes have one of two phenotypes, $Lyt2^+$, $L3T4^-$ or $Lyt2^-$, $L3T4^+$, which make up 3–5% and 8–15% of murine thymocytes, respectively[20,23]. The fourth subpopulation is negative for both Lyt2 and L3T4 markers and represents only 3–4% of thymocytes. Some of these cells bear low levels of the Ly1 surface antigen, a fact important for their initial isolation[20]. Thus their phenotype is $Ly2^-$, $L3T4^-$, $Ly1^{dull}$ and they have been called dull Ly1 (dLy1) cells. They are large, blast-like cells and may correspond to the blast cells with a similar phenotype that are found early in the developing fetal thymus[23]. dLy1 cells isolated with a purity of 97% have several properties indicating that they are T-cell precursors[19,20]. When cultured *in vitro*, 25–30% differentiate within 20 h to cells with the $Lyt2^+$, $L3T4^+$ phenotype. This experiment extends the observation of Ceredig *et al.* showing that $Lyt2^-$ precursors differentiate *in vitro* to $Lyt2^+$ thymocytes[24]. More importantly, adoptive transfer experiments indicate that these isolated cells re-enter and transiently repopulate the thymus of congenic irradiated recipient mice. Donor-derived cells with both the $Lyt2^-$, $L3T4^-$ and cortical ($Lyt2^+$, $L3T4^+$) phenotypes appear first in the thymus. Within 10–20 days after transfer, donor-derived cells have differentiated into thymocytes with the phenotypes of immunocompetent T cells ($Lyt2^+$, $L3T4^-$ and $Lyt2^-$, $L3T4^+$). However, cells in the dLy1 population have certain properties which distinguish them from

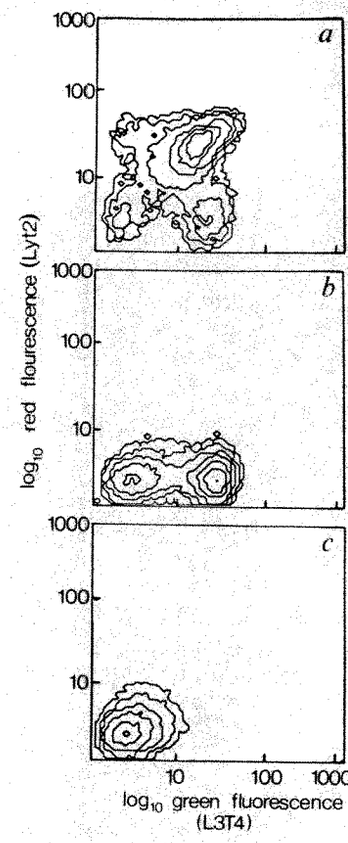

Fig. 1 Two-colour flow cytometric analysis of Lyt2 and L3T4 on B6 thymocytes during the isolation of the precursor thymocyte population. Thymocyte suspensions from C57BL/6 mice (6–8 weeks old) were prepared as described elsewhere[20]. Cells were incubated for 30 min at 4 °C with a saturating concentration of antibody, then washed twice in Hank's balanced salt solution with 0.1% bovine albumin and 0.1% sodium azide and resuspended for the next incubation. The sequence of reagent incubation for panel *a* was: (1) anti-L3T4 culture supernatant[25], (2) fluorescein isothiocyanate-labelled goat anti-rat immunoglobulin, (3) normal rat serum, (4) biotin-labelled rat anti-Lyt2[26], (5) Texas-red avidin. Flow cytometry was performed on a fluorescence activated cell sorter[19]. *a*, Unfractionated thymocytes. *b*, $Lyt2^-$ thymocytes, isolated as previously described[19]. Briefly, $20–30 \times 10^8$ thymocytes were incubated with anti-Lyt2.2 ascites fluid and rabbit complement. Viable cells were obtained by purification on Ficoll–Paque (Pharmacia). Cells were washed three times. *c*, Isolated $Lyt2^-$, $L3T4^-$, $Ly1^{dull}$ (dLy1) cells. $Lyt2^-$ cells were treated with anti-Ly1.2 ascites, purified anti-L3T4 antibody and complement, and again purified by centrifugation over Ficoll.

bone marrow-derived stem cells that can also repopulate the thymus, including a limited capacity for self-renewal, and the ability to give only a single wave of differentiation that generates the other three phenotypes in the thymus. Although studies on the functional properties of these dLy1 cells and their progeny remain to be performed, these data suggest that the dLy1 cells represent a population of precursor thymocytes at an intermediate developmental stage between marrow-derived stem cells and immunocompetent T cells.

The expression of RNA encoding T-cell antigen receptor proteins was assayed in the dLy1 precursor population to determine whether these early thymocytes were transcribing receptor genes. Total cytoplasmic RNA was analysed by Northern blotting with α-(TT11)[2] and β-(86T5) chain[26] cDNA probes (Fig. 2). These experiments reveal that the dLy1 cells as well as unfractionated thymocytes contain the 1.3- and 1.0-kilobase (kb) β-gene transcripts shown to represent *V-D-J* and *D-J* rearrangements respectively [9,10]. In this experiment the precursor (dLy1) cells contained β-chain-specific transcripts in a concentration approximately equal to the unfractionated cell. This indicates that within the highly purified dLy1 population, at

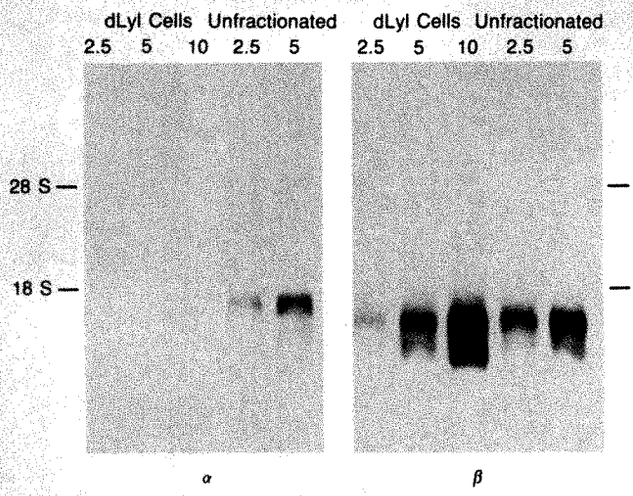

Fig. 2 Northern blot analysis of thymocyte and dLyl RNA to reveal α- and β-chain gene expression. Cells ($0.9–2.5 \times 10^8$) were homogenized in 4 M guanidinium thiocyanate and RNA was purified by centrifugation through CsCl[29]. The RNA was denatured in 2.2 M formaldehyde, and the indicated amount of RNA (μg) electrophoresed in a 1% agarose gel with 0.2 M formaldehyde, then transferred to nitrocellulose. The probe used to detect α-chain gene expression was the *Rsa*I to *Ava*II fragment comprising the constant region of the TT11 cDNA clone[2]. The 86T5 cDNA clone was used to detect β-chain gene expression[27]. Probes were labelled by nick-translation. Hybridization was in 5 × SSPE, 1 × Denhardt's solution, 10% dextran sulphate and 50% formamide at 42 °C. The blots were washed twice in 2 × SSPE, 0.1% SDS at 55° C and once in 0.2 × SSPE at 55 °C.

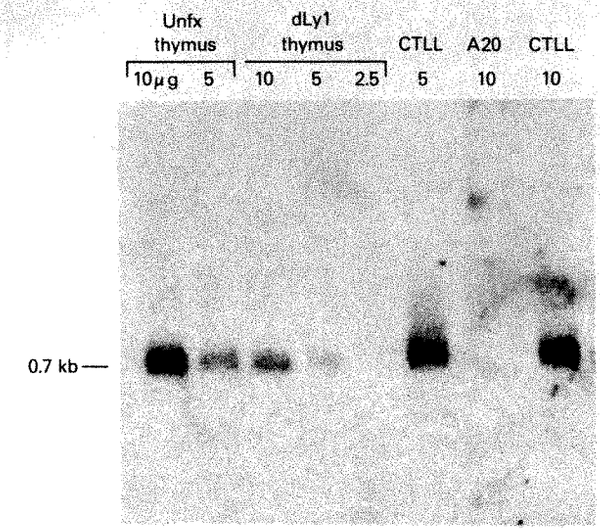

Fig. 3 Northern blot analysis with the T3 δ-chain probe. The RNA and blots were prepared as described in Fig. 2. The blots were prehybridized at 42 °C for 2 h in 50% deionized formamide, 5 × SSC, 5 × Denhardt's solution, 50 mM sodium phosphate, *p*H 6.5, 0.1% SDS with 250 mg ml^{-1} denatured salmon-sperm DNA. Hybridization was carried out in the same buffer for 16 h at 42 °C. The mouse T3 δ-chain cDNA insert of clone PEM-T3δ[28] was nick-translated and used as a hybridization probe. Following hybridization, blots were washed three times in 2 × SSC, 0.1% SDS at 25° C and twice in 0.1 × SSC, 0.1% SDS at 50° C.

least some cells transcribe RNA for the β-chain gene product. When the same blot was probed with the α-chain cDNA clone TT11, however, essentially no hybridizing RNA was observed in the dLyl population. Since the dLyl cells is an early thymocyte, these data suggest that α-chain RNA expression follows β-chain gene expression in intrathymic T-cell maturation.

The T-cell antigen receptor in mature T cells is associated with three molecules comprising the T3 complex. A cDNA insert of the clone PEM-T3δ, which encodes the murine T3 M_r 20,000 glycoprotein δ-chain[28], was used to probe the dLyl thymocyte population (Fig. 3). The probe hybridized to RNA from the purified dLyl population as well as to RNA from unfractionated thymus and the mature T-cell line CTLL, but not with A20 B-cell RNA. As RNA for this product is expressed in the dLyl population, this gene product is not likely to be limiting in the assembly of the T-cell antigen/receptor complex. Expression of RNA for the β-chain of the antigen receptor and the T3 δ-chain are thus both early events in T-cell maturation.

To analyse antigen receptor genes of early T cells at a clonal level, we fused purified precursor thymocytes with the drug-marked thymoma BW5147, reasoning that these large, proliferating immature cells would fuse readily with the thymoma line. They would thus behave like pre-B cells derived from fetal liver, which fuse efficiently to plasma cell lines[30]. Indeed, we observed a high frequency of fusions in such an experiment (1 in $5–10 \times 10^4$). Twelve of these lines were tested for the presence of the Thy 1.2 allele, a T-cell marker donated by the B6 dLyl cells and not by the AKR-derived Thy 1.1 BW5147 cells. Of these 12, 9 expressed the expected marker from the input cells, implying, though not proving, that they derived from fusions involving cells of the T lineage[31]. These cells were also stained with antibodies binding Lyt2 and L3T4 and were all negative for these markers, consistent with a dLyl ($Lyt2^-$, $L3T4^-$) origin.

DNA was isolated from these 12 lines and subjected to Southern blot analysis (Fig. 4*a*, *b*). Germline B6 mouse DNA digested with the restriction enzyme *Pvu*II gave three tightly migrating, though not always well-resolved, bands of 6.4, 6.2 and 6.0 kb hybridizing with the 86T5 β-chain probe. DNA from the BW5147 thymoma cell showed two non-germline bands at 6.5 and 5.8 kb, resulting from two separate rearrangements to the $C_\beta 2$ locus (R. Lechler and R.N.G., N. E. Lee and M.M.D., unpublished results). The hybrids have a combination of BW5147-derived bands, germline bands, and additional bands presumably representing rearrangements in the precursor population. Eight hybrids possess such additional rearrangements in their DNA, whereas four Thy 1.2^+ hybrids (1G8, 1G10, 2C9 and 2E5) contain non-BW5147 hybridizing bands of only germline pattern. To confirm the finding that these four hybrids had only germline bands of B6 origin, further analysis of these DNA preparations after digestion with the restriction enzymes *Hpa*I (Fig. 4*b*) and *Hin*dIII (data not shown) was performed. The additional experiments indicated that these four hybrids had all the expected germline and BW5147-derived restriction fragments without any additional bands. Thus an analysis with three restriction enzymes revealed that, while many hybridomas showed β-locus rearrangements consistent with the observed transcription of β-chain genes in the dLyl population, a substantial fraction of the hybrids retained nonrearranged β-chain genes.

The pattern of α- and β-chain gene expression in the dLyl and total thymocyte populations, together with these data on β-locus rearrangements in dLyl-derived T hybridomas, suggest three distinct patterns of T-cell antigen receptor gene rearrangement in developing thymocytes. Two of these subpopulations exist within the dLyl precursor population. The first, characterized on the basis of four hybrids, has germline β-chain and, because α transcripts are absent in dLyl cells, apparently unrearranged α-chain gene loci. The analysis of genomic DNA from eight additional hybrids defines a second subpopulation with rearranged β-chain, and by the same reasoning, germline α-chain genes. One can infer the existence of a third subpopulation, not present among dLyl cells, in which both gene loci are rearranged, as thymocytes bearing a mature α/β heterodimer[33] and an intact T3 complex[34] have been demonstrated with monoclonal antibodies. Although the T3 δ-chain gene is expressed in the dLyl subpopulation, no information yet exists to place expression of the other T3 components in this scheme.

The characterization of the first two of these subpopulations depends on certain assumptions about the fusion of dLyl cells

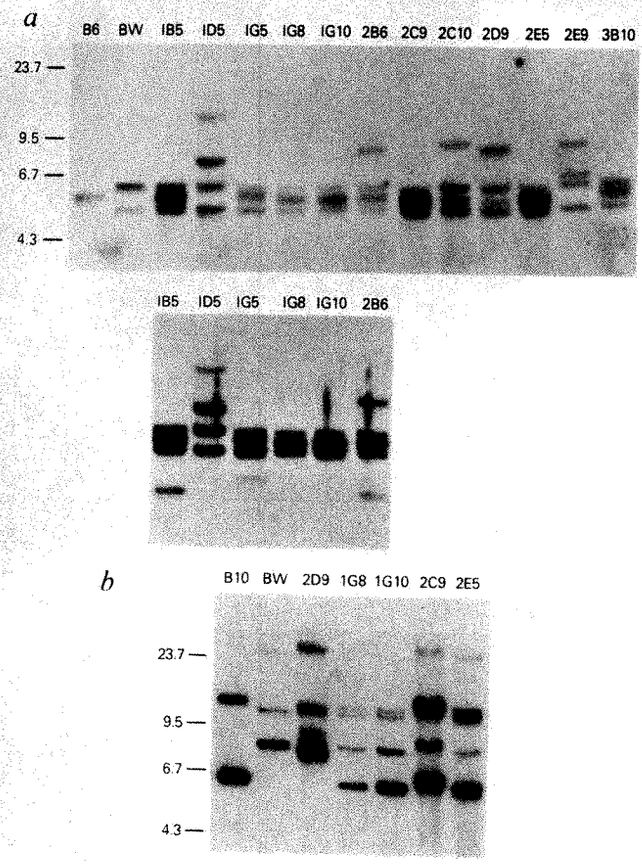

Fig. 4 Southern blot analysis of genomic DNA from dLyl hybridomas. dLyl cells were isolated as described in Fig. 1 and fused to the drug marked thymoma BW5147 with polyethylene glycol. Hybridomas were selected in hypoxanthine/aminopterin/thymidine medium. DNA was prepared from the cells by standard methods[32], digested with the restriction enzyme *Pvu*II (*a*) or *Hpa*I (*b*), electrophoresed through 0.7% agarose and blotted onto nitrocellulose. The 86T5 β-chain probe was used for hybridization and the blots were washed three times in 2 × SSC, 0.1% SDS at 25° C and three times in 0.2 × SSC, 0.1% SDS at 60° C. The inset represents a longer exposure of the blot in panel *a*. Germline DNA from liver is included in the first lane.

with the BW5147 thymoma line. First, that contaminating cells of other (non-dLy1) phentoypes did not fuse to the BW5147 thymoma. An analysis of those non-dLy1 cells showed that most had a mature phenotype and thus were likely to contain predominantly small resting cells that might not fuse without stimulation (Yeh *et al.*[35] and L.E.S., unpublished data). Furthermore, the 12 hybrids randomly chosen for DNA analysis bore the expected Lyt2$^-$, L3T4$^-$ phenotype of the dLy1 cell. Second, because the dLy1 population seems heterogeneous for a series of other cell-surface markers (B.J.F., unpublished data), it is possible that there was preferential fusion involving a subpopulation of dLy1 cells such as those with germline β-chain loci. The proportion of hybridomas that have germline β-chain genes may not accurately reflect the true fraction of dLy1 cells with this phenotype. We assume, however, that these cells are in the T-cell lineage because all bear the Thy 1.2 surface marker.

Because the relationships among the various thymocyte subpopulations remain disputed[16], it is not possible to make direct correlations between the various patterns of α- and β-chain gene expression described here, and a single, linear pathway of T-cell development. Nevertheless, the three distinct T-cell rearrangement patterns can be related to stages of the better-defined B-cell differentiation process[36]. In the B lineage, the heavy-chain genes first undergo rearrangement, followed by the appearance of intracellular μ proteins in the pre-B cell. Only after subsequent light-chain gene rearrangement and expression has occurred does the complete immunoglobulin molecule appear on the surface of the mature B cell. In the T lineage, at some point after commitment, cells with non-rearranged α- and β-chain genes can be found. The four hybrids with germline β-chain gene loci may be examples of such cells, although it remains to be shown that these cells have germline α-chain genes and are not cells of a lineage that do not use the β-chain gene locus (for example, suppressor T cells[37]). By analogy to B-cell development[38], we propose the name 'pro-T' cells for this committed precursor subpopulation. Cells of the second subpopulation are analogous to the pre-B cell. These pre-T cells have rearranged one of their receptor genes, β, and express RNAs corresponding to both *D–J* (1.0 kb) and *V–D–J* (1.3 kb) rearrangements. Although we have no evidence for *D–J* rearrangement preceding *V–D–J* as the 1.0- and 1.3-kb mRNAs are present in equal amounts, such a progression may occur[39] as in B cells[40,41]. At some later stage, the α-chain genes are rearranged and transcribed, giving rise to the complete receptor on the mature T cell. Such a sequence of rearrangements also seems to occur in the fetal thymus[42]. In the experiments of Raulet *et al.*, however, a preponderance of 1.0-kb β-chain RNA is seen in the fetal thymus, perhaps because during ontogeny the developmental steps are better synchronized. The complexity of events within this maturational scheme may account for the large number of β gene clones corresponding to *D–J* type rearrangements that were isolated from a thymocyte library[9]. A *V*-containing β-chain gene product may be needed before α-chain gene rearrangement, accounting for the relatively low level of α-chain transcripts in the thymus[2]. Although cells with characteristics of pro-T and pre-T stages can be found in the immature dLy1 population of thymocytes, and the thymus contains some T cells with mature phenotype and antigen receptors, further experiments are necessary to determine if differentiation through these stages takes place entirely or solely within the thymus. Repopulation experiments with isolated pro-T and pre-T cells should provide further insight into these issues.

We thank Drs R. Asofsky, N. Braunstein, R. Lechler and J. Miller for helpful discussions, Ms L. Edison for FACS analysis and Ms S. Starnes for editorial assistance. Erythropoietin is the primary physiological regulator of erythropoiesis; however, *in vitro* studies have identified another class of mediators which appear to be important in stimulating erythroid progenitors. These factors have generally been referred to as burst-promoting activities (BPA), because they stimulate the growth of early erythroid progenitors referred to as burst-forming units-erythroid (BFU-E) which give rise to colonies of up to thousands of haemoglobinized cells[1,2]. We recently reported purification of a burst-promoting activity from medium conditioned by the Mo T-lymphoblast cell line infected with human T-cell lymphotropic virus type II (HTLV-II)[3,4]. This purified glycoprotein of relative molecular mass (M_r) 28,000 also stimulates colony formation by more mature erythroid precursors (CFU-E) and is therefore referred to as erythroid-potentiating activity (EPA)[5]. Purified EPA specifically stimulates human and murine cells of the erythroid lineage, unlike murine interleukin-3 (IL-3) which stimulates precursor cells from all haematopoietic lineages[6]. We report here the isolation of a complementary DNA molecular clone encoding EPA and its use in producing EPA in COS (monkey) cells and CHO (Chinese hamster ovary) cells. We also define the organization of the EPA gene in human DNA.

Purified EPA obtained from two 10-l preparations of medium conditioned by the Mo T-lymphoblast cell line was analysed in four separate samples using a gas phase sequenator. From a total of approximately 25 μg of purified protein, the following partial amino-acid sequence was obtained from the NH_2-terminus:

```
1          5          10         15         20         25
(A) T C V P P H ? Q T A F C N S D L V I R A K F V G T
```

Using this sequence, three different oligonucleotide probes were prepared. The first probe consisted of all 64 possible 12-mers encoding residues 9-12 above (QTAF). The second probe consisted of 64 14-mers predicted from residues 21-25 (AKFVG). The third probe was a pool of 16 53-mers predicted from residues 9-26 based on preferred codon usage. A cDNA library was prepared from Mo messenger RNA and enriched for sequences specific to mature T cells by hybridizing the single-stranded cDNA to mRNA from B cells (Daudi) and immature T cells (CEM). One set of replicate filters containing the enriched Mo cDNA library was hybridized with the 64 12-mers and the other set with the 64 14-mers described above. DNA from 10 clones which hybridized with both probes was prepared and analysed by digestion with *Pst*I and hybridization to each of the three oligonucleotide probes. Three clones, each of which had at least one internal *Pst*I site, hybridized to all three probes, and were further characterized.

A pool of eight strongly hybridizing 14-mers (corresponding to amino-acid residues 21-25) was used as a primer for sequencing the three putative EPA cDNA clones. The resulting DNA sequence was that expected from the amino-acid sequence of

Fig. 1 Nucleotide and deduced amino-acid sequence of the cDNA clone encoding EPA.

Methods. Standard gentle lysis procedures were used to prepare RNA from 2×10^9 lectin-stimulated Mo cells. Polyadenylated RNA was selected with oligo(dT)-cellulose and used as the template to synthesize the first strand of cDNA by reverse transcription. Approximately 1 μg of single-stranded cDNA, obtained from 10 μg of poly(A)$^+$ RNA, was enriched by hybridization to 10-fold excess concentrations of mRNA from a human B-cell line (Daudi) and immature T-cell line (CEM), and the unhybridized cDNA (~5% of input cDNA) was recovered by chromatography on hydroxylapatite. Standard techniques were used to synthesize the second cDNA strand, digest the single-stranded loop and add homopolymeric (dC) tails. The cDNAs were annealed with G-tailed pBR322 and used to transform *Escherichia coli*. A final yield of 40,000 colonies was obtained from double-stranded cDNA. EPA was purified from serum-free Mo-conditioned medium using the previously published method[3]. Two preparations of EPA containing ~25 μg were subjected to Edman degradation and analysed on a gas phase sequenator. Based on the amino-acid sequence obtained, three pools of oligonucleotide probes were constructed. The pools were used to probe replicate filters containing the recombinant plasmids described above. Potential EPA clones were identified by colony hybridization. DNA from positive clones was analysed by restriction digestion and hybridization to the oligonucleotide probes. EPA cDNA clones were verified by DNA sequence analysis using the dideoxynucleotide chain termination procedure primed with the oligonucleotides described in the text[19].

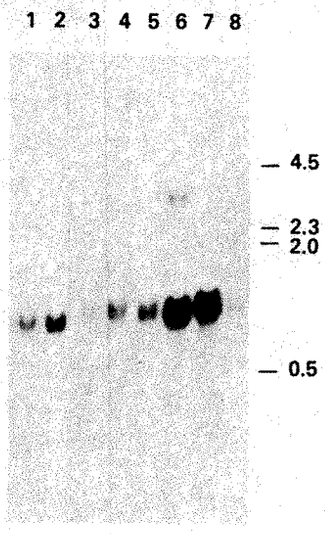

Fig. 2 Analysis of EPA mRNA from human cells and cell lines. Polyadenylated cytoplasmic RNA (5 μg) was isolated from U-937 cells cultured in the presence of 10 nM dexamethasone for 20 h (lane 1); U-937 cells (lane 2); Mo cells cultured in the presence of dexamethasone (lane 3); Mo cells (lane 4); Mo cells treated for 20 h with phytohaemagglutinin (0.3%) and phorbol myristate acetate (5 mg ml^{-1}) (lane 5); C10-MJ2 cells (lane 6); UCD-144-MLA cells (lane 7); and peripheral blood lymphocytes (lane 8). The mRNA was fractionated on a 1% agarose gel, transferred to nitrocellulose and hybridized with the EPA clone labelled with ^{32}P as described previously[12].

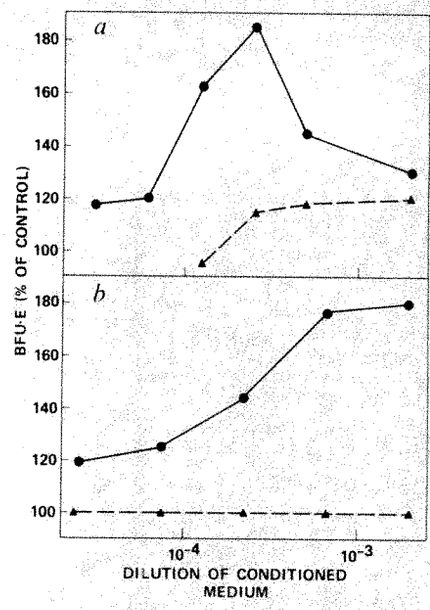

Fig. 3 Biological activity of EPA cDNA clones expressed in mammalian cells. *a*, Stimulation of human peripheral blood BFU-E by dilutions of supernatants containing recombinant EPA expressed transiently in COS cells (●) compared with mock-transfected COS cells (▲). *b*, Supernatant from CHO cells which constitutively produce high levels of recombinant EPA (●) compared with supernatant from a CHO line which does not express the EPA cDNA (▲).

Methods. The expression vector 91023(B) is described in detail elsewhere[17]. This plasmic contains eukaryotic regulatory elements from adenovirus, simian virus 40, and the mouse immunoglobulin and dihydrofolate reductase genes. COS 7 monkey cells were transfected with the EPA cDNA inserted into the 91023(B) vector using a previously described procedure[12]. Briefly, cells were incubated for 12 h at 37 °C in serum-free Dulbecco's modified Eagle's medium containing DEAE-dextran (M_r 5×10^6 Pharmacia, 250 mg ml^{-1}) with 0.1 M Tris *p*H 7.3 and 2 μg ml^{-1} plasmid DNA. After the incubation, cells were rinsed with serum-free medium and treated for 2 h at 37 °C with 1 mM chloroquine in medium containing serum. Cells were washed and medium was collected at varying intervals. Chinese hamster ovary cells (CHO) were transfected with the 91023(B) vector containing the EPA cDNA clone and a functional dihydrofolate reductase clone subcloned into the unique *Cla*I site. Stable transfectants were isolated by selection in growth medium without nucleosides for about 2 weeks. The transfected DNA containing the EPA sequence was amplified by repeated stepwise selection in methotrexate for ~2 months. To determine the levels of recombinant EPA protein synthesized, supernatants from transiently infected COS cells and stably infected CHO cells were analysed in a radioimmunoassay for EPA (J.C.G., J. Chan and D.W.G., in preparation). Samples which were positive for immunoreactive EPA were assayed for biological activity, by measuring stimulation of the growth of human peripheral blood BFU-E in methylcellulose culture[3]. Peripheral blood leukocytes were plated at a density of 3×10^5 cells ml^{-1} in 96-well tissue culture trays. Each well contained 0.1 ml of cells in methylcellulose and 0.01 ml of a dilution of the test supernatant. Control wells were those to which diluent alone was added, and they contained 20 colonies per well in panel *a* and 16 colonies per well in panel *b*.

residues 1-19, confirming that these cDNA clones encode the EPA protein.

The complete nucleotide sequence of all three clones was obtained by dideoxy sequencing of M13 subclones (Fig. 1). The cDNA encodes a protein of 207 amino acids. Based on the NH_2-terminal sequence of the mature protein, a signal peptide of 23 amino acids is predicted by the nucleotide sequence. Characteristic of other signal peptides, this region is rich in hydrophobic amino acids. The predicted relative molecular mass of the mature protein is in good agreement with the apparent 18,000 M_r observed following digestion of EPA with endoglycosidase F (ref. 4). Endoglycosidase F removes both high mannose and complex asparagine-linked carbohydrate moieties[7]; two possible sites for asparagine-linked glycosylation are amino acid 53 and 101. The presence of 12 cysteine residues in the deduced amino-acid sequence predicts a protein structure which could account for the marked heat stability previously described for EPA biological activity[5].

The EPA cDNA clone was used to screen a cDNA library prepared from the gibbon lymphosarcoma cell line UCD-144-MLA[8], a source of numerous lymphokines including burst-promoting activity. The resulting clones were sequenced and compared with the nucleotide sequence of human EPA. Seven nucleotides within the coding region differed between human and gibbon EPA, resulting in a single amino acid change from arginine to lysine at residue 43.

Further confirmation that these clones encode EPA was obtained by Northern analysis. mRNA was prepared from cells previously shown to produce burst-promoting activity. Figure 2 shows that Mo (lane 4), C10-MJ2[9] (lane 6) and UCD-144-MLA[8] (lane 7) mature T-lymphoblast cell lines, peripheral blood lymphocytes (lane 8) and the U-937[10] (lane 2) monocytic cell line produce a 0.9-kilobase (kb) transcript which hybridizes with the EPA cDNA probe. Erythroid-potentiating activity mRNA could not be detected in samples from the immature B-lymphoblastoid cell line Daudi (data not shown). These results are in agreement with previous reports of EPA activity, as well as the presence or absence of the EPA protein in cell supernatants as determined by immunoprecipitation and radioimmunoassay (unpublished results). Treatment of U-937 (Fig. 2, lane 1) and Mo (lane 3) cells with the glucocorticoid dexamethasone appears to decrease the level of EPA mRNA by approximately twofold. Similar results have been seen with other T-cell-derived growth factors including IL-2[11] and granulocyte-monocyte colony-stimulating factor (GM-CSF)[12]. Treatment of Mo cells with phytohaemagglutinin and phorbol myristate acetate (Fig. 2, lane 5) does not greatly increase the abundance of EPA mRNA over that produced constitutively. In similar conditions, GM-CSF mRNA levels are increased approximately two- to fourfold[12].

To provide definitive evidence that the cDNA clone encoded EPA, it was expressed in mammalian cells. The EPA cDNA

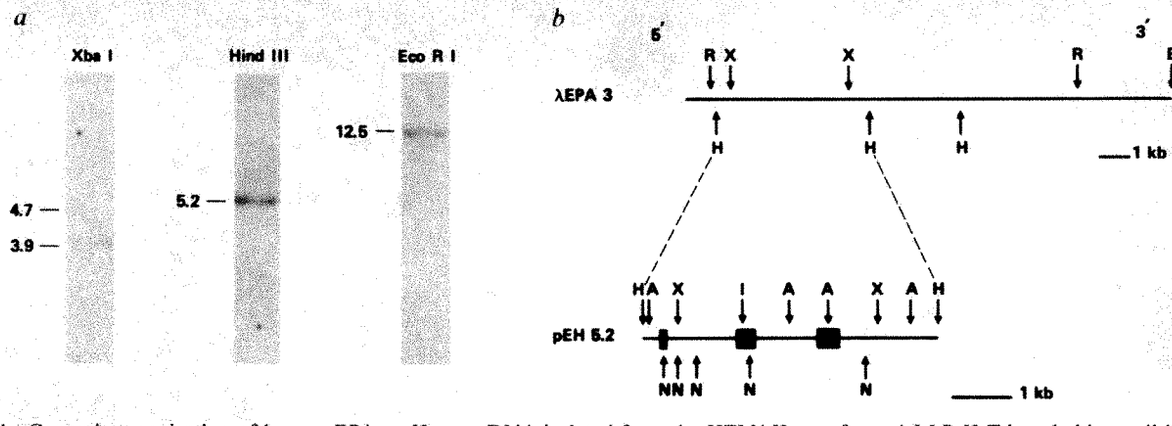

Fig. 4 Genomic organization of human EPA. *a*, Human DNA isolated from the HTLV-II-transformed J-LB-II T-lymphoblast cell line was digested with *Xba*I, *Hin*dIII and *Eco*RI and hybridized with the EPA cDNA. *b*, Restriction map of an EPA genomic clone in Charon 30 (λ EPA 3) and subcloned into pBR322 (pEH 5.2) are shown. Restriction sites are: R, *Eco*RI; X, *Xba*I; H, *Hin*dIII; A, *Ava*I; N, *Nco*I; I, *Hin*cII. **Methods.** High M_r DNA was prepared from a variety of cell lines, using standard procedures. The lengths of restriction fragments containing EPA sequences were determined by the method of Southern[12]. A λ phage recombinant library was constructed using Charon 30 and DNA from the J-LB-III human T-lymphoblast cell line[20]. The J-LB-III DNA was digested with the restriction enzyme *Sau*3A for various times and 10–25-kb fragments were isolated using a NaCl gradient[21]. The J-LB-III DNA was ligated to Charon 30 DNA which had been digested with *Bam*HI and purified on a NaCl gradient. Recombinant phage were recovered by *in vitro* packaging[22]. The recombinant phage were screened by hybridization to a probe consisting of a full-length EPA cDNA clone. Two smaller fragments of the EPA cDNA clone were isolated using *Pst*I, gel purified and used to generate detailed restriction maps of the EPA genomic clones.

clone was inserted into the 91023(B) mammalian expression vector and transiently expressed in COS monkey cells[13]. The concentration of EPA in the unfractionated COS cell supernatants was estimated, by radioimmunoassay, to be approximately 1 μg ml^{-1} 72 h after transfection, indicating efficient expression of the cDNA clone.

Supernatants from COS cells transiently infected with either the 91023(B) vector alone or the vector containing the EPA coding region were assayed for stimulation of human peripheral blood BFU-E. The results (Fig. 3*a*) demonstrate biological activity of the recombinant EPA transiently expressed in COS monkey cells. Good stimulation of erythroid bursts (>130% of control) is seen at concentrations as low as ~5 pM (based on the concentration of immunoreactive EPA). In every case, the supernatant from the mock-infected or uninfected COS cells had a slight stimulatory activity on human BFU-E, apparently due to some constitutive production by COS cells of a factor that stimulates human erythroid precursors.

In addition to transient expression of EPA in COS cells, it is useful to generate cell lines which constitutively produce high levels of EPA protein. Chinese hamster ovary cells with integrated copies of the 91023(B) vector containing the EPA coding region along with the dihydrofolate reductase gene were selected in methotrexate. After approximately 2 months of selection, levels of EPA protein in supernatants from 31 CHO cell clones were estimated by radioimmunoassay. One clone was found to constitutively produce levels of recombinant EPA similar to those obtained by transient expression in COS cells. The biological activity of recombinant EPA in the medium conditioned by this cell line was compared with medium conditioned by CHO cells which had been treated in the same way, but were not producing recombinant EPA. Figure 3*b* shows the stimulation of human peripheral blood BFU-E by recombinant EPA produced by this stable line of CHO cells. No endogenous burst-promoting activity is seen in the supernatant from CHO cells not producing recombinant EPA. The recombinant EPA is active in the picomolar range of concentrations, as is the purified protein from Mo-conditioned medium[3].

To study the molecular organization of the human EPA gene sequences, high-M_r DNA was prepared from human T-cell lines (J-LB-II, J-LB-III, J-WM-IV, Mo), B-cell lines (Wil), a myeloid line (HL-60) and a fibroblast line (143) and analysed by the method of Southern[14] for hybridization to the EPA cDNA clone. In all cases the same pattern was seen (Fig. 4*a*). The restriction enzyme *Xba*I generated a strongly hybridizing fragment of 3.9 kb and a faint band at 4.7 kb. A single fragment of 5.2 kb and 12.5 kb was detected following digestion with *Hin*dIII and *Eco*RI respectively.

To obtain a more detailed map of the structure of the EPA gene, a recombinant λ phage library (prepared from Charon 30[15] and J-LB-III DNA) was screened with the EPA cDNA clone as a probe. Three overlapping genomic EPA clones were obtained from approximately one million recombinant phage. The restriction map of one representative clone, λ EPA 3, is shown in Fig. 4*b*. This clone contains the 12.5-kb *Eco*RI fragment and the 5.2-kb *Hin*dIII fragment which was subcloned into pBR322 for further analysis (pEH 5.2). Restriction analysis of pEH 5.2 revealed that EPA appears to be encoded by a single gene approximately 3 kb in length, interrupted by at least two intervening sequences.

Human EPA specifically stimulates the growth of peripheral blood- and bone marrow-derived erythroid precursors from mouse and man. Il-3 is a 28,000-M_r glycoprotein isolated from the EL-4 mouse lymphoma cell line and WEHI-3 mouse myelomonocytic cells. Unlike EPA, IL-3 stimulates the growth of all haemotopoietic precursors, including BFU-E[6]. Murine IL-3 has been molecularly cloned and sequenced[16,17]. Comparison of the murine IL-3 sequence with the human EPA sequence, described here, reveals no homology. Thus EPA is not the human counterpart of murine IL-3, consistent with the biological observations that EPA does not stimulate pluripotent or myeloid precursor cells[3,4].

A computer search for protein homology did not reveal previously described proteins homologous to EPA (R. Doolittle, personal communication). A computer search for DNA homology (Genbank) did, however, reveal that a highly homologous partial murine cDNA clone had been isolated. This clone was obtained from virally induced C243 cells using hybrid selection of mRNAs whose translation products have antiviral interferon activity[18]. The cDNA clone pMIF 3/10 contains about 290 base pairs that could encode that 3′ 39 amino acids of a protein plus the 3′-untranslated region. This cDNA clone was reported to encode a murine β-interferon-like protein, but the relationship between this molecule and EPA is unclear. Erythroid-potentiating activity has no interferon activity (our unpublished observation), and full-length cDNA clones of pMIF 3/10 have not been isolated and expressed to provide direct evidence for interferon activity.

The physiological functions of EPA *in vivo* are unknown. Since EPA stimulates murine erythroid precursors *in vitro*, as well as human, it should be possible to study *in vivo* effects of this modulator in the mouse. The availability of adequate quan-

ties of recombinant protein will be critical in elucidating the role of EPA in normal haematopoiesis. Additionally, the availability of cDNA and genomic clones will make it possible to study the evolution and expression of this interesting erythroid haematopoietic growth factor.

We thank Noelle Bersch for performing the bioassays, Irvin S. Y. Chen for helpful comments on the manuscript and Hillary Merriman and Betty Koers for preparation of the manuscript. Myxococcus xanthus spore coat protein S may have a similar structure to vertebrate lens $\beta\gamma$-crystallins

Graeme Wistow*, Lesley Summers† & Tom Blundell†‡

* Laboratory of Molecular and Developmental Biology, National Institutes of Health, Building 6, Room 211, Bethesda, Maryland 20205, USA

† Laboratory of Molecular Biology, Department of Crystallography, Birkbeck College, University of London, Malet Street, London WC1E 7HX, UK

The Gram-negative bacterium *Myxococcus xanthus* has a complex life cycle[1] during which large amounts of a protein of relative molecular mass (M_r) 19,000, known as protein S, are assembled into a spore surface coat by a process that specifically requires calcium ions[2,3]. The gene for protein S has been cloned and the DNA sequence shows that the gene product is composed of four internally repeated homologous sequences, each 40 amino acids long[4]. Although protein S resembles calmodulin both in its internally duplicated structure and its ability to bind calcium[4], it apparently has a β-sheet secondary structure[5] rather than the helix–loop–helix motifs that characterize the calmodulin family[6–8]. We now show that protein S has a striking homology with the β- and γ-crystallins of the vertebrate eye lens[9–11] which are β-sheet proteins with internally duplicated structures. This implies that the β- and γ-crystallins evolved from already existing proteins, whose ancestors occurred in the prokaryotes. The biological function of protein S, as a closely packed, stable protein in a relatively dehydrated environment, has implications for the functions of crystallins, which are found closely packed in the lens fibre cells, where their stability is essential for maintenance of transparency.

γ-Crystallin has an internally repeated sequence of ~40 amino acids[9–11] arranged as two globular domains related by a pseudo-dyad. Each domain is formed from two Greek key motifs (strands *d a b c*) related by further pseudo-dyads and arranged as two antiparallel β-sheets, each sheet composed of strands *c' d a b* where strand *c'* is contributed by one motif and *d a b* by the second. In motif 1 the characteristic fold is made possible by the presence of a glycine at position 13 which allows the β-hairpin formed by strands *a* and *b* to fold back on to the sheet so that the peptide nitrogen of residue 11 hydrogen-bonds to the buried side chain of serine 34 which just precedes strand *d*. This leads to interactions between the aromatic amino acids at residues 6 and 11, which are protected from solvent by an arginine at residue 36. This arrangement is repeated in the other motifs with a small variation in sheet 3 only[10]. The amino-acid sequences of the β- and γ-crystallins from several species[12–19] have this arrangement of residues in common, suggesting an evolutionary relationship between the two crystallin classes and the existence of a protein structural superfamily, the $\beta\gamma$-crystallins[17].

Analysis of the repeated sequences of bovine γ-crystallin II(γ_{II}) shows that motifs γ1 and γ3, and motifs γ2 and γ4 have the strongest homologies. Motifs γ2 and γ4 are longer than γ1 and γ3, and appear to have several residues inserted in the loop region between strands *c* and *d* of the Greek key motifs. A similar analysis of protein S shows that S1 and S3, and S2 and S4 are the pairs with the highest homologies (60% and 45%), indicating a similar pattern of duplication, but greater similarity between the two halves than in $\beta\gamma$-crystallins. The optimum correspondence of repeated sequences between protein S and γ_{II} is nonlinear (Fig. 1). In terms of the number of residues, the S2/S4 pair corresponds most closely to motif γ1 of γ-crystallin II. Similarly, S1/S3 corresponds most closely to motifs γ2 and (not shown) γ4. At the level of sequence identity also, S2/S4 most closely resembles γ1, with 33% and 23% identity respectively, whereas S1/S3 matches γ2/γ4, with 26% identity between S1 and γ2 and 19% identity between S3 and γ4. The N-terminal domain of γ_{II} (γ1γ2) was used as the basis for a model for both proposed domains of protein S. Figure 2 shows a model structure for S1S2, the N-terminal domain of protein S. The structurally important residues are all present, allowing the main chain to follow the same path, forming the characteristic folded hairpin structure described for γ (refs 9, 10). The

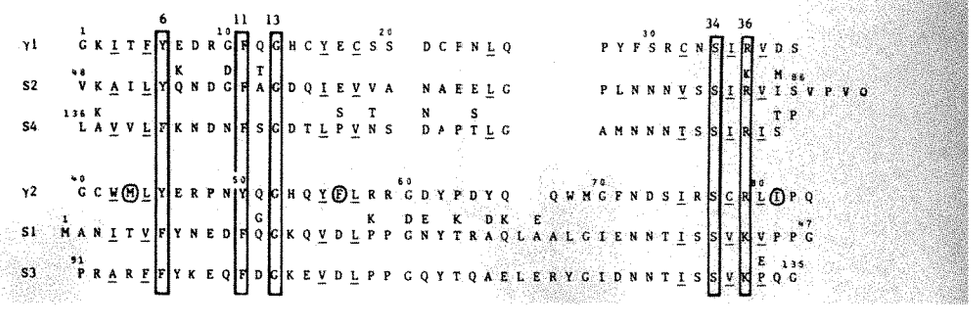

Fig. 1 Alignment of the four repeated sequences of protein S (S1–S4) with the first two motifs of γ-crystallin II (γ1, γ2). The protein S sequence is that defined for gene 2, with the residues for gene 1 given above; there is an inserted alanine between Ser 146 and Gly 147 in gene 1.

‡ To whom correspondence should be addressed.

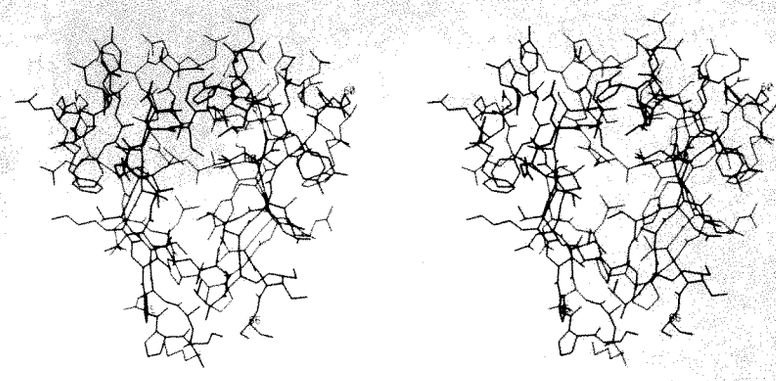

Fig. 2 A stereo view of the molecular model of one domain (S1 + S2) of protein S. The model was constructed by first aligning the sequences of protein S and bovine γ_{II} so that the structurally important glycine and serine residues coincide. The alignments are shown in Fig. 1. To simplify the comparison, only one motif of each pair in γ_{II} is shown. The two domains were modelled using the N-terminal domain of γ_{II} (comprising motifs $\gamma1\gamma2$) as a guide, with γ_{II} coordinates taken from the structure refined at 1.6 Å resolution[11]. The interactive graphics program FRODO (ref. 25, modified by T. A. Jones and I. J. Tickle) run on an Evans and Sutherland PS2 was used for model-building in the manner described previously for bovine βBp-crystallin[26] and murine β23-crystallin[18]. Main-chain atoms were not moved, except where two insertions were required in a surface loop of $\gamma2$ to model S1 and S3. The coordinates of invariant side chains were retained. For conservative changes, side-chain conformations were modelled closely on the crystallographic coordinates; remaining side chains were modelled to optimize favourable interactions and to avoid disallowed non-bonded contacts. The models have been subjected to energy minimization.

extensive hydrogen-bonding in the β-sheets and elsewhere[10] is also preserved.

Because of the non-sequential correspondence between related motifs, it was necessary to make and break inter-motif connections in the γ_{II} structure; this is easily achieved as each domain contains a pseudo 2-fold axis, the N-terminus of each strand *a* and the C-terminus of each opposing strand *d'* being disposed in space in a similar way (Fig. 3). We have attempted to build a model with sequential alignment of the two polypeptides, but it gives less good packing of the hydrophobic core.

The model shown in Fig. 2 indicates that the residues which occupy the space between the two sheets in each domain (S1S2 or S3S4) of protein S are conserved as hydrophobic, although there is a small overall decrease in their volume (see Fig. 1). For example, Tyr 16 of $\gamma1$ and the topologically equivalent Tyr 55 of $\gamma2$ which lie on strand *c* at the edge of the sheet are replaced by leucine, valine or isoleucine in protein S. More importantly, the buried Trp 42 is replaced by isoleucine in S1 and an alanine in S3. However, the inserted residues in the loop between strands *c* and *d* in S1 and S3 of protein S appear to contribute to the core packing, and Gly 70 of $\gamma2$ is replaced by isoleucine in protein S. Molecular mechanics calculations imply that the two β-sheets are packed more closely in protein S than in γ-crystallin II, while preserving the hydrophobicity of the contacts. Similar small relative shifts in β-sheet positions have been shown to occur in the azurin/plastocyanin family[20]. The exact relationship of the two sheets must await a detailed X-ray analysis, which is now underway[21].

In β-crystallins the two domains ($\gamma1\gamma2$ and $\gamma3\gamma4$) are related by a further pseudo-dyad which gives rise to closely packed hydrophobic interactions between residues of strands *a*, *b* and *d* of $\gamma2$ and $\gamma4$, involving residues which are conserved as hydrophobic in all $\beta\gamma$-crystallins. In motifs S1 and S3 of protein S, these are replaced by several charged groups, indicating hydrophilic contacts with solvent. However, inter-domain contacts may instead be formed between the sheets that are mainly composed of motifs S2 and S4, where hydrophobic residues do occur. Most of the surface residues of protein S are hydrophilic and many are charged, although the unusually large number of ion pairs found in γ-crystallin II, for example, Arg 36 to Asp 61 (refs 9, 10), are absent from protein S. Protein S is more acidic than γ-crystallin II, mainly because of the smaller number of arginines/lysines rather than an increase in the number of acidic residues. As in γ-crystallin II, there is a predominance of aspartates over glutamates.

Overall, the proposed structure for protein S is consistent with the data presented by Inouye *et al.*[4,5]. In particular, the inter-domain connecting peptide, as in bovine γ_{II}, would be relatively exposed and potentially vulnerable to tryptic cleavage (in the case of protein S). The so-called 'tryptic core structure'[4] would thus correspond to the first domain of protein S.

Calcium ions are thought to be specifically involved in binding protein S to spores. The existence of layers of protein S which are 300 Å thick[2] indicates that there may be intermolecular interactions between protein S molecules (maximum dimension ~80 Å) as well as with specific receptors on the spore. Because identical crystals of protein S may be obtained with or without calcium[5,21] and as calcium binding has no significant effects on the circular dichroism of protein S[5], protein S may be crosslinked to its receptors on the spore and possibly to other protein S molecules directly through surface Ca^{2+} sites which do not affect the conformation of the molecule.

As there is no direct evidence implicating any particular residues in calcium binding, we began by searching the model surfaces of the protein S gene 1 and 2 products for conserved arrangements of oxygen ligands, for example carboxylates of aspartate or glutamate, amides of asparagine or glutamine, O_γ of serine or threonine, and peptide carbonyl oxygens. Such calcium-binding ligands have been identified in a wide range of proteins. The most obvious candidate is a surface group of four acidic residues found close to the folded β-hairpin structure and including residues Glu 10, Glu 70, Glu 71 and Asp 11 (see Fig. 4); this would give only one binding site for calcium per protein S molecule and would be consistent with the ability of only ~45% of the 'tryptic core structures' to self-assemble on the protein S-deficient spores, as only one of the two domains would bind calcium. An alternative binding site occurs in each of the sequences S1 to S4 and therefore occurs twice in each domain. This binding site is composed of the conserved topological equivalent residues Glu 10, Glu 99, Asp 56 and Asp 144. The other ligands at each of these putative calcium-binding sites are derived from the conservatively varied sequence Glu 35-Asn 36-Asn 37-Thr 38-Ile 39-Ser 40 and equivalents of this, represent-

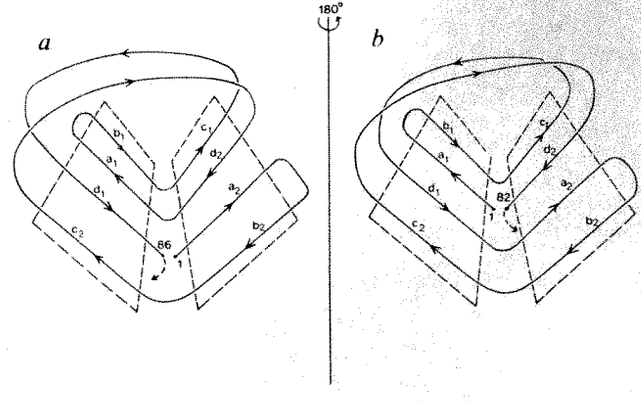

Fig. 3 The suggested arrangement of the strands in the first two repeated sequences (S1 and S2) of protein S (*a*) compared with that found in γ-crystallin II (*b*).

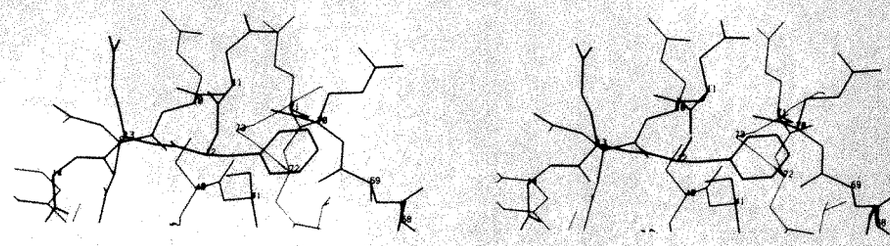

Fig. 4 A stereo view of a possible calcium-binding site involving Glu 10, Asp 11, Glu 70 and Glu 71.

ing part of the sequence Glu 35 to Lys 43 which has been identified by Inouye *et al.*[22] as homologous to the calcium-binding sequence of calmodulin. However, if our model is correct, the binding cannot involve Ser 41, as this residue is buried. There is no residue in protein S corresponding to the final glutamate which is conserved in the loop region of all members of the calmodulin family. These sites are the most obvious candidates for surface Ca^{2+} binding.

Finally, we must consider the implications of the observed structural similarity between protein S and $\beta\gamma$-crystallins for the function and evolution of vertebrate lens proteins. The putative calcium-binding sites described above are not generally conserved in bovine γ_{II} or in other $\beta\gamma$-crystallins[12-19]. However, calcium ions do seem to have an effect on the aggregation of crystallin in certain systems[23]. Lens proteins have a short-range order which leads to slowly changing protein concentrations and a smooth change of refractive index through the transparent lens; conceivably, this could be influenced by calcium, suggesting a specific role for ions in certain forms of cataract.

γ-Crystallins and protein S are highly stable molecules[24]; this may be due to the closely hydrogen-bonded structure of the repeated Greek key motifs, which lack the loose external loops found in many proteins, and to their symmetrical, tightly packed arrangements. Thermodynamic stability may be a general consequence of protein structures developed to survive for long periods in relatively dehydrated environments without turnover; this would apply to both spore proteins and lens crystallins.

γ-Crystallins have high proportion of cysteine and aromatic residues which are not found in protein S. None of the six cysteines found in $\gamma1\gamma2$ is retained in protein S. The two tryptophans in γ-crystallin are replaced by aliphatic residues and the loss of 10 phenylalanines and tyrosines is compensated for by only three at other positions. It has been argued[10,11] that the cysteines and associated aromatic amino acids are important in protecting the lens proteins from the effects of ultraviolet radiation and other abuses which lead to free radical formation. These aspects of the $\beta\gamma$-crystallin structure may have evolved to meet the special requirements of the lens.

The intramolecular homology of protein S indicates that a pattern of gene duplication similar to that proposed for $\beta\gamma$-crystallins has occurred. The fact that S2 resembles $\gamma1$ and S1 resembles $\gamma2$ suggests that a common ancestor could have been an asymmetrical dimer of two 40-residue units. In the crystallin line of descent, the genes for these molecules were fused in the order $\gamma1$–$\gamma2$ while the reverse order occurred for protein S. In both cases, further duplication and fusion led to the present two-domain structures.

We thank Christine Slingsby, Huub Driessen, Raghu Sarma and Masayori Inouye for helpful discussion. We acknowledge the use of the SERC computer graphics workstation. We thank Linda Miller and John Bouquiere for help with illustrations and Dawn Sickles and Glenda Dryer for typing the manuscript. G.W. is a Fogarty Fellow at NIH.

We have shown previously that *Drosophila* cells contain virus-like particles (VLPs) containing 5-kilobase (kb) RNA that hybridizes to a transposable element, termed *copia*. We have suggested that VLPs and *copia* are derivatives of viral particles and proviral forms, respectively, of '*copia*' retrovirus, a putative *Drosophila* retrovirus[1]. To further clarify the relationship between *copia* and *copia*-related RNA in VLPs (VLP H-RNA), we determined and compared their nucleotide sequences. VLP H-RNA was found to be an unspliced, genome-sized transcript of *copia*, and, like retroviral genome RNA, VLP H-RNA is terminally redundant with termini localized in the long terminal repeats (LTRs) of *copia*. VLP H-RNA contains two long open reading frames (ORFs), one of which includes the coding sequence for a predominant VLP protein of relative molecular mass (M_r) 31,000 (31K). Here we show that, in contrast to *17.6* ORF2 (ref. 2), ORFs of *copia* have no extensive amino-acid sequence homology to the RT region[2] of the reverse transcriptase of retrovirus in vertebrates. Because of a one-base insertion/deletion, the two ORFs in VLP H-RNA are fused and become a single, longer ORF in a genomic *copia*.

Using cDm2055 DNA[3] as a probe, we isolated 20 recombinant phage containing *copia* from a cloned library of *Drosophila melanogaster* DNA[4] and made restriction maps (data not

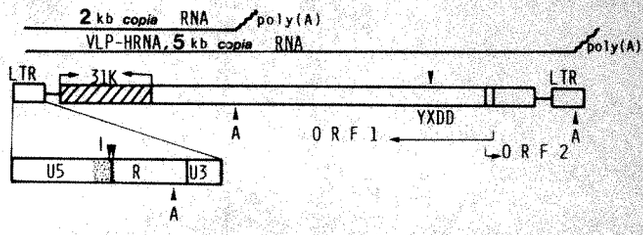

Fig. 2 Genome organization of *copia* and its gene products shown schematically. The 5′ LTR has been enlarged to make the internal structure of LTR more easily discernible. The ambiguity in the 5′ end of U3 results from the three consecutive A residues at the poly(A) attachment site, whereas that of R results from the real heterogeneity in the 5′ end of VLP H-RNA. Two downward arrows labelled I show the positions of the 5′ ends of the two major VLP H-RNA. The locations of the putative polyadenylation signal of *copia*, AAATAATAAATC, are shown by the arrows labelled A. Note that one of the polyadenylation signals is near the region corresponding to the 3′ end of 2-kb *copia* RNA. The structure of genomic *copia* is based on the sequence of VLP H-RNA, although a *copia* in λcop88 contains a single ORF covering the entire regions of both ORFs 1 and 2 (see Fig. 1). A polypurine tract similar to those of other *Drosophila* transposons and vertebrate retroviruses[12] can be seen in the 3′-untranslated region. The expected coding sequence of the predominant 31K VLP protein is shown by a shaded box and appears to be included in both 2- and 5-kb *copia* RNA (VLP H-RNA). The location of the most conservative amino-acid sequence among RNA dependent polymerases, Y(M, L, V or G)DD(hydrophobic amino acid)$_3$, is shown by the arrow at YXDD. Association of 31K VLP protein and VLP H-RNA is considered to result in the production of VLP.

Fig. 1 (Opposite) Nucleotide sequences of *copia* and cDNA of *copia*-related RNA in VLP (VLP H-RNA). The complete nucleotide sequence of *copia* in λcop88 is shown as the putative sense strand in L1, whereas L3 and L3′, respectively, show the composite cDNA nucleotide sequence of VLP H-RNA and the DNA sequence complementary to the 5′ terminal sequence of VLP H-RNA determined by the dideoxy-chain termination method using VLP H-RNA as a template. The ranges of long ORFs found in both *copia* and VLP H-RNA are shown by L-shaped arrows labelled ORF, with amino-acid sequences shown below the corresponding nucleotide sequences (L2 and L4). Dashes, nucleotide or amino-acid sequences identical to those of *copia* in L1 and L2. 0s in L3 indicate one-nucleotide deletions in VLP H-RNA, whereas # denotes the termination codon of each ORF. Underlines, nucleotide sequences corresponding to the duplicated target DNA; *a* and *i*, 5′ start sites of cellular 2- and 5-kb RNA[6]; *b*, expected polyadenylation signal; *c*, *e*, *h*, nucleotide sequence complementary to the 26-nucleotide long synthetic oligodeoxynucleotide for primer extension experiments; *d*, the amino-acid sequence best conserved among various polymerases[10,11]; *f*, polypurine sequence corresponding to the counterparts of other *Drosophila* transposons and vertebrate retroviruses (*g*)[12]. Overlines labelled *w* and *y*, respectively, show the 5′ terminal region of VLP H-RNA in the 5′ LTR and its equivalent in the 3′ LTR. Two vertical arrows indicate 5′ ends of two major VLP H-RNAs. Thin lines associated with the arrows show the degree of inaccuracy (±1 nucleotide) for the determination of 5′ ends. Overlines *z* and *x* exhibit the poly(A) attachment site of VLP H-RNA in the 3′ LTR and its equivalent in the 5′ LTR, respectively. The ranges of 5′ LTR, 3′ LTR and expected coding region of the predominant M_r 31,000 VLP protein (31K) are shown by L-shaped arrows. The end of the 31K region was tentatively determined based on the relative molecular mass and amino-acid composition of the 31K VLP protein. The base substitutions and deletion found in the nucleotide sequences of *copia* regions 1–1,143 and 2,302–2,931 (described in refs 6, 7) are shown by small letters and *o*, respectively, above the *copia* sequence (L1).

Methods. The nucleotide sequence of *copia* was determined by digesting DNA extracted from λcop88 by various restriction enzymes and recloning the resultant DNA segments containing *copia* pieces using plasmid pUC9 (ref. 13) as a cloning vector. Sizes and locations of the cloned DNA segments are shown by thick lines with arrows and numbers in scheme *A*. After *Escherichia coli* cells (JM83 (ref. 13) harbouring a desired plasmid) were cultured in 5–10 ml L-broth for 12–15 h at 37 °C with shaking, plasmid DNA was prepared by the alkali method[14]. Contaminated RNA was removed by a treatment of 10 μg ml^{-1} of RNase for 30 min at 37 °C and final concentration of 7.5% polyethylene glycol in 0.94 M NaCl for 1 h at 0 °C. Nucleotide sequence was determined by the chain termination method[15] modified by M. Hattori (unpublished) using the DNA cloned in pUC9. Two different kinds of synthetic oligonucleotides [M13 single-stranded primer (5′ GTAAAACGACGGCCAGT3′) and M13 reverse sequence primer (5′ CAGGAAACAGCTATGAC3′) (P-L Biochemicals)] were used as primers for sequencing. The overall strategy for sequencing is depicted by thin underlines in the lower margin illustration (*A*). Scale bar; 1,000 bp; the two boxes show the LTRs. Restriction enzyme cutting sites used are as follows: a, *Acc*I; b, *Bam*HI; c, *Cla*I; e, *Eco*RI; h, *Hin*dIII; l, *Bal*I; p, *Hpa*I; s, *Pst*I; t, *Aat*I; v, *Pvu*II; x, *Xba*I. The nucleotide sequence of VLP H-RNA was determined as follows. As described previously[1], VLP was purified from a 5 l culture of GM_2 cells and total VLP RNA extracted. After the VLP H-RNA was purified by gel electrophoresis, cDNA was constructed and cloned into pBR322 using the procedures described by Maniatis *et al.*[16]. Restriction mapping and blot hybridization allowed overlapping of the cDNA inserts obtained and a composite restriction map of the cDNA of VLP H-RNA to be made. The restriction map obtained was found to be very similar to that of *copia*. Thus, in scheme *B*, their relative positions are depicted using the restriction map of the *copia* in λcop88 as a reference. Plasmid DNA was purified essentially as described elsewhere[2]. The complete or partial nucleotide sequences of A-25, G-19, G-29, G-34, G-46, J-15, J-16, J-19, H-15 and 3-5 were determined by the procedures of Maxam and Gilbert[17]. We found no discrepancy in the nucleotide sequence in the overlapped region. The position of poly(A) attachment site in G-29 was identical to that in 3-5. Thus, in L3, the composite sequence is shown as the nucleotide sequence of the cDNA of VLP H-RNA. We consider the sequence shown in L3 to be identical to that of VLP H-RNA, apart from the DNA–RNA difference, because (1) at its 3′ end, it contains a long poly(A) tract, a typical terminal structure of eukaryotic mRNA and retroviral genome RNA; and (2) a separate experiment (not shown) indicated that only the DNA strand of *copia*, complementary to the one whose sequence is shown in L1, is hybridizable to VLP H-RNA. The nucleotide sequence near the 5′ terminus of VLP H-RNA was determined by the chain termination method[15]. After 3 μg VLP RNA and 65 ng of ^{32}P-labelled oligodeoxynucleotide (see Fig. 4*a*) in 40 μl 0.1 M NaCl, 1 mM EDTA and 10 mM Tris-HCl (*p*H 8.3) was preincubated at 85 °C for 5 min, then at 60 °C for 10 min. 10 μl 500 mM Tris-HCl (*p*H 8.3) containing 50 mM dithiothreitol and 80 mM $MgCl_2$, 1 μl RNasin, 1 μl reverse transcriptase and 8 μl 25 μM dCTP were added. To each of four 14-μl aliquots, 8 μl of the dNTP-ddNTP mixture of M13 sequencing kits (Takara Shuzo Ltd, Japan) was added. The resultant mixture was then incubated at 40 °C for 20 min. After four dNTPs (1 mM each) in 4 μl was added, the incubation was continued for further 20 min. The reaction products were precipitated by adding 2.5 μl 3 M sodium acetate (*p*H 5.2) and 2 vol ethyl alcohol, and subjected to gel electrophoresis for sequencing.

shown). As the restriction map of the *copia* in λcop88 was very similar to that of most of the *copias* that we cloned, the complete nucleotide sequence of the *copia* in λcop88 was determined as representative of *copia* sequences (Fig. 1, L1). The *copia* in λcop88 is 5,143 base pairs (bp) in length and terminates with 276-bp LTRs whose nucleotide sequences are identical or very similar to the published LTR sequences of other *copias*[5]. Partial nucleotide sequences of the region flanked by LTRs have been reported elsewhere[6,7]. The sequences in these studies are essentially identical to the counterparts described here (Fig. 1). Translation of the nucleotide sequence showed that *copia* contains a long ORF, ORFg (Fig. 1, L2), residing on a DNA strand corresponding to the major cellular *copia* RNAs[6].

We purified VLP H-RNA by gel electrophoresis and made complementary DNA clones. We found no clones that completely covered the entire region of the VLP H-RNA; the information from the 5′ end of the RNA could not be recovered because S_1 nuclease was used. Nevertheless, the overlapping of several cDNA clones (Fig. 1) allowed us to determine 97% of the total sequence of VLP H-RNA from its 3′ end (Fig. 1, L3). The nucleotide sequence of the major portion of the residual 3% was determined by the chain termination method using VLP H-RNA as a template (Fig. 1, L3′). These results show that the nucleotide sequence of VLP H-RNA corresponds to the *copia* sequence shown in Fig. 1 (L1) except for some minor base changes and a terminal poly(A) tract. Because of a deletion of an A residue located somewhere between residues 4,220 and 4,224, the ORF of *copia* (ORFg) is split in two, slightly overlapping ORFs 1 and 2 in VLP H-RNA (Fig. 1). The 3′ end of VLP H-RNA that lacks poly(A) is located in the 3′ LTR of *copia*. However, we found no AATAAA, a typical signal for polyadenylation, in this LTR. The sequence AAATATAAATC is present ~20 nucleotides upstream from the poly(A) attachment site of the 5-kb RNA and in the region expected for the 3′ terminus of the 2-kb RNA (ref. 6; Figs 1, 2). This sequence, or part of it, may function as a polyadenylation signal in *copia*.

To determine the location of the 5′ end of VLP H-RNA, we carried out a primer extension experiment using total VLP RNA and ^{32}P-labelled, 26 nucleotide long synthetic oligodeoxynucleo-

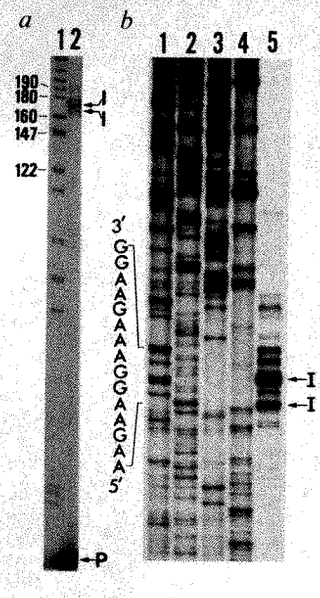

Fig. 3 Determination of the 5′ end of VLP H-RNA by primer extension. The expected locations of the 5′ ends of two major VLP H-RNAs are shown by arrows labelled I, whereas the arrow labelled P shows that of the 26-nucleotide-long primer used. *a*, pBR322 DNA was digested with *Hpa*II, labelled with ^{32}P by kinase treatment, denatured and used as a marker. Molecular sizes in the left margin are in bp. Using total VLP RNA (3 μg) and 26-nucleotide-long synthetic DNA (65 ng) (see Fig. 4*a*) as a template and primer, a primer extension experiment was carried out essentially according to Treisman *et al.*[18]. After the reaction, samples were denatured, applied to 45-cm-long 8% polyacrylamide gel in the presence of 7 M urea, and electrophoresed. Lane 1, pBR322 marker; lane 2, products of primer extension of VLP RNA with primer. *b*, Numbers in lanes 1–4 show the nucleotide sequence pattern obtained by the modified dideoxy-chain termination method when the DNA of plasmid 15 (see scheme *a* in Fig. 1) and the 26-nucleotide-long synthetic DNA identical to that used for primer extention of VLP RNA (Fig. 4*a*) were used as a template and primer. Lanes 1, 2, 3 and 4, respectively, show the locations of G, A, T and C residues. The sample in lane 5 is an aliquot of the reaction products shown in lane 2 in *a*.

tide (see Fig. 4*a*). Two intensive bands, 166 and 172 nucleotides in length, along with ~20 less intensive bands of similar size, were observed (Fig. 3), suggesting that VLP H-RNA is heterogeneous in the location of its 5′ end. By comparing the positions of these bands (Fig. 3*b*, lane 5) with the dideoxy-chain termination pattern of the 5′ terminal region of *copia* (lanes 1–4), we determined the range of the 5′ ends of VLP H-RNA (Fig. 1, overline *w*). According to Flavell *et al.*[6], the 5′ ends of cellular *copia* RNA are similarly heterogeneous in sequence and localized in an almost identical region in the 5′ LTR of *copia* (see Fig. 1). Taking together their findings and the results described above, we conclude that VLP H-RNA is an unspliced genome-sized transcript of *copia* (see Fig. 2). As with vertebrate retrovirus, VLP H-RNA has terminal redundancy, 77–116 nucleotides in length, and the *copia* LTR can be divided into three regions, 106–142 bp (U5), 77–116 bp (R) and 54–57 bp (U3) (Fig. 2). These findings provide additional evidence for the notion that *copia* RNA may be reverse-transcribable[1,8].

VLP H-RNA has weak messenger RNA activity and can be translated into polypeptides immunologically related to VLP proteins[1]. To identify the coding region for the predominant 31K VLP protein[1], the partial amino-acid sequence of one of the polypeptides obtained from the 31K protein was determined and found to be identical to that of the amino-terminal region of the polypeptide expected to be derived from ORFg of *copia* (or ORF1 of VLP H-RNA) (Fig. 4*b*). Furthermore, the calculated amino-acid composition of the M_r 31,000 amino-terminal

Fig. 4 *a*, Nucleotide sequence of a 26-nucleotide-long synthetic oligonucleotide used as the primer. It is complementary to a portion of *copia* sequence (see underline *d* in Fig. 1, L1) and was synthesized using a Model 380A synthesizer (Applied Biosystems). *b*, Comparison of the partial amino-acid sequence of the predominant 31K protein of VLP and that of the amino-terminal region of the putative ORFg (or ORF1) protein of *copia*. X, an unidentified amino acid.

Methods. VLP was purified from a 12-l culture as described previously[1] and the predominant 31K protein purified by large-scale SDS-polyacrylamide gel electrophoresis. The 31K VLP protein was treated with cyanogen bromide[19] and the resultant polypeptides separated and purified by reverse-phase liquid chromatography (RP300 (4.6×250 mm), Brown Lee). The partial amino-acid sequence of the major polypeptide was determined by stepwise Edman degradation using a gas-phase automated sequencer (Model 470 A, Applied Biosystems). The recovery of other polypeptides was low because of self-aggregation.

portion of the putative *copia* ORFg (ORF1) polypeptide was found to be almost identical to that observed for the 31K VLP protein (data not shown). Thus, we suggest that the coding region for the 31K VLP protein is located in the 5′ terminal region of the ORFg (ORF1) (Figs 1, 2*b*) and the 31K VLP protein is one of the cleavage products of the putative polypeptide(s) expected to be produced from ORFg (or ORF1).

To determine whether *copia* has the coding sequence for the reverse-transcriptase-like enzyme associated with VLP[1], we compared the amino-acid sequences of ORFs 1 and 2 with those of the reverse transcriptases of retroviruses[9] and equivalent polypeptides of *Drosophila* transposons such as *17.6* (ref. 2). However, no appreciable homology could be seen except for Tyr-(Met, Leu, Val or Gly)-Asp-Asp(hydrophobic amino acid)$_3$, the most conservative sequence among various polymerases[10,11], near the carboxy-terminus of the ORFg (ORF1) polypeptide(s) (Figs 1, 2). This suggests that *copia* contains the coding region for the reverse-transcriptase-like enzyme, which has a different amino-acid sequence from the counterparts of other *copia*-like elements[2] and retroviruses[9]. Furthermore, this reduced homology partly results from the extensive rearrangement within the putative *pol* region of *copia* (the region between nucleotides 1,242 and 4,658 in Fig. 1; K.S. *et al.*, unpublished).

We thank Drs T. Miyake, T. Uchida, T. Miyata and T. Yamazaki for critical comments. M. Hattori for informing us of his new protocol of nucleotide sequencing and K. Hattori, Y. Suzuki and M. Kobayashi for assistance. This work was partly supported by grants from the Ministry of Education, Science and Culture, Japan to K.S.

Phosphorylation of the glucose transporter *in vitro* and *in vivo* by protein kinase C

Lee A. Witters*‡, Carol A. Vater† & Gustav E. Lienhard†

The Ca^{2+}- and phospholipid-dependent protein kinase (protein kinase C) is present in many mammalian tissues[1], and its important physiological protein substrates are only now beginning to be identified. A useful advance in identifying these intracellular substrates has been the recognition that the kinase is the receptor for phorbol esters, which stimulate phosphotransferase activity[2–4]. Phorbol ester-induced changes in protein phosphorylation in intact cells may thus be taken, in part, as a probable indication of protein kinase C activation. The many cellular effects of phorbol esters include the stimulation of glucose uptake[5–8], although the response of glucose uptake to phorbol esters appears to be complex, apparently varying in response time and requirement for protein synthesis[6,7]. Such observations prompted us to explore one possible explanation for the alteration of glucose uptake, namely, phosphorylation of the glucose transporter by protein kinase C. We report here that incubation of purified human erythrocyte glucose transporter with rat brain protein kinase C results in the phosphorylation of a protein of relative molecular mass (M_r) 50,000–60,000 which has subsequently been identified as the glucose transporter by specific immunoprecipitation with a monoclonal antibody. Immunoprecipitation of membrane proteins from ^{32}P-labelled human erythrocytes revealed a phorbol ester-stimulated phosphorylation of the transporter. This covalent modification of the glucose transporter may thus, in part, underlie the ability of phorbol esters and certain hormones to stimulate glucose uptake.

Incubation of a preparation of purified human erythrocyte glucose transporter with protein kinase C resulted in the phosphorylation of a protein that migrated on SDS-gel electrophoresis as a broad band of apparent M_r 50,000-60,000 (50-60K), together with higher-M_r species, some of which did not enter the SDS gel (Fig. 1*a*). The phosphorylation was absolutely dependent on the addition of Ca^{2+}; because the transporter preparation contained erythrocyte membrane phospholipids, added phosphatidylserine caused only a slight increase in phosphorylation. It has been shown previously that the transporter is a glycoprotein that migrates as a broad band of apparent M_r 50-60K on SDS gels, due to heterogeneity in its oligosaccharides[9,10]. In addition, on incubation with detergents, the protein has a tendency to form dimers and higher-M_r aggregates which is not prevented by reducing agents[10,11]. No phosphorylation of these bands was observed on incubation with casein kinase I, casein kinase II or the catalytic subunit of the cyclic AMP-dependent protein kinase (not shown). Because the preparation of glucose transporter used in these experiments was only 70–80% pure[11], the identity of the ^{32}P-labelled protein as the transporter was established unequivocally by specific immunoprecipitation with a monoclonal antibody directed against the erythrocyte transporter (antibody G3)[12] (Fig. 1*b*). The bands at M_r ~100,000 and at the top of the gel seen in Fig. 1*b* (and in Fig. 3*b*) are due to the dimer and the higher-M_r aggregates of the transporter[10,11].

Nearly 0.5 mol of ^{32}P-phosphate per mol cytochalasin B binding was incorporated into the transporter on prolonged incubation with protein kinase C (Fig. 2*a*). Although the purified transporter is contained in largely unsealed membranes of erythrocyte lipids[11,13], it is possible that not all of the potential phosphorylation sites are exposed to the kinase or that the preparation already contains phosphorylated amino acids. Limited acid hydrolysis of ^{32}P-labelled transporter and subsequent thin-layer electrophoresis revealed only ^{32}P-phosphoserine (not shown). HPLC separation of ^{32}P-phosphopeptides, generated by prolonged tryptic digestion, yielded only one ^{32}P-peptide (Fig. 2*b*) which also contained only ^{32}P-phosphoserine. These data support the conclusion that the phosphorylation is confined to a single protein in the transporter preparation and probably to a limited number of phosphorylation sites.

To determine whether protein kinase C phosphorylates the glucose transporter *in vivo*, human erythrocytes were labelled with $^{32}P_i$ and exposed for 20 min to phorbol 12-myristate 13-acetate (PMA), 4α-phorbol didecanoate (inactive phorbol; 4αPDD) or dimethyl sulphoxide (DMSO), the solvent used. We found that PMA, but not 4αPDD, stimulated the phosphorylation of two easily identifiable proteins in ^{32}P-labelled membranes (Fig. 3*a*). These seem to correspond to band 4.1 (M_r 80K), as reported previously in rabbit erythrocytes[14], and a minor ^{32}P-phosphoprotein of M_r 125K. ^{32}P-labelled membrane protein was solubilized and immunoprecipitated with the monoclonal antibody. Specific immunoprecipitation of ^{32}P-labelled transporter indicated that the transporter was phosphorylated in intact cells in the basal state and that the phosphorylation increased substantially in response to PMA (Fig. 3*b*).

These data suggest that phorbol ester-stimulated glucose uptake may be, in part, a consequence of protein kinase C-

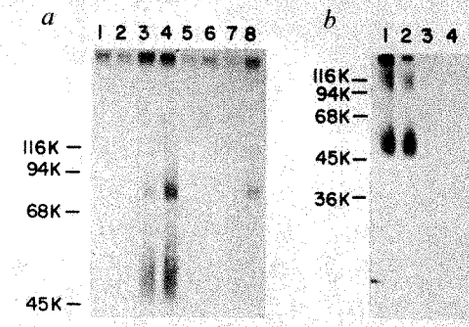

Fig. 1 *In vitro* phosphorylation of glucose transporter by protein kinase C (*a*) and ^{32}P-protein identification by immunoprecipitation (*b*). In *a*, human erythrocyte glucose transporter (55 μg ml^{-1}; lanes 1–4) or buffer (lanes 5–8) was incubated for 30 min with [γ-^{32}P]ATP (100 μM), $MgCl_2$ (10 mM) and protein kinase C (4,000 pmol units ml^{-1}) in the presence of EGTA (1 mM; lanes 1, 5), EGTA plus phosphatidylserine (PS) (40 μg ml^{-1}; lanes 2, 6), $CaCl_2$ (1 mM; lanes 3, 7), and $CaCl_2$ plus PS (lanes 4, 8). No phosphorylation of any protein was observed in the absence of added kinase. In *b*, aliquots of the incubations of the transporter with added kinase were immunoprecipitated with monoclonal antibody to the transporter (lanes 1, 2) or with control monoclonal antibody (lanes 3, 4), and the immunoprecipitates separated by SDS-gel electrophoresis before autoradiography. Lanes 1, 3, kinase reaction with $CaCl_2$ and PS; lanes 2, 4, kinase reaction with $CaCl_2$ alone. M_r markers are indicated on the left of *a* and *b*.

Methods. The glucose transporter from human erythrocytes was purified by the method of Baldwin *et al.*[11]. Protein kinase C was partially purified from rat brain through the gel filtration step by the method of Kikkawa *et al.*[1]; the kinase used in these experiments had a specific activity of 200 nmol per min per mg protein against histone III-S. Kinase assays were performed by the method of Parker *et al.*[4]. Immunoprecipitation was carried out by solubilization of the transporter (1 μg) in 1.5% octyl glucoside, followed by incubation of the samples on ice with 1.5% octyl glucoside/protein A-Sepharose to which 10 μg of the specific or control monoclonal IgG was complexed. The immune complexes were washed and then solubilized with 1.0% SDS in the absence of reducing agents and without heating. SDS gels were run according to Laemmli[24].

‡ Present address: Endocrine-Metabolism Division, Department of Medicine, Dartmouth Medical School, Hanover, New Hampshire 03756, USA.

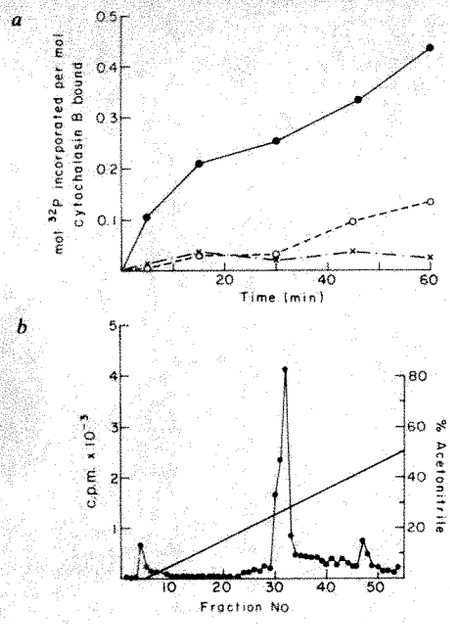

Fig. 2 Time course and stoichiometry of glucose transporter phosphorylation (*a*) and HPLC separation of tryptic ^{32}P-phosphopeptides (*b*). In *a*, the glucose transporter preparation was phosphorylated with protein kinase C in the presence (●) and absence (○) of added $CaCl_2$ and in the absence of added kinase (×), as in Fig. 1, and ^{32}P incorporation quantitated by trichloroacetic acid (TCA) precipitation in the presence of carrier bovine serum albumin. Control values for kinase autophosphorylation have been subtracted from total ^{32}P incorporation. Results are expressed as mol ^{32}P incorporated per mol cytochalasin B binding (taken as 1 binding site per mol functional transporter). Cytochalasin B is a high-affinity ligand for the transporter. Its binding provides a measure of the amount of functional transporter in a preparation, which is typically ~60% of the protein weight[11]. In *b*, phosphorylated transporter was precipitated with TCA, washed and digested with 20% trypsin (w/w) at 37 °C for 18 h. The solubilized ^{32}P-peptides were separated by HPLC with C_{18} reverse-phase chromatography using an ascending gradient of acetonitrile in H_2O/0.1% trifluoroacetic acid. When the same procedure was applied to a control reaction mixture containing only protein kinase C, no significant peak of ^{32}P-peptide was found.

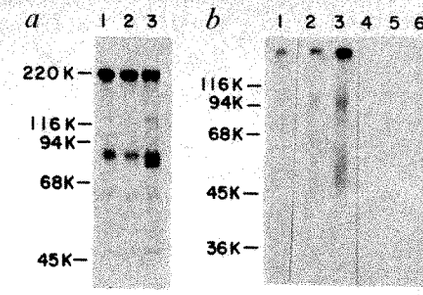

Fig. 3 Phorbol ester-stimulated protein phosphorylation of human erythrocyte membrane proteins (*a*) and glucose transporter, as determined by immunoprecipitation (*b*). In *a*, human erythrocytes were labelled with $^{32}P_i$, and membranes prepared by the method of Patel and Fairbanks[25]. Labelled cells were exposed for 20 min to phorbol 4α-didecanoate (1 μM, lane 1), DMSO (0.1%, lane 2) and phorbol 12-myristate 13-acetate (lane 3), before cell lysis. Membrane protein (20 μg) from each sample was separated on SDS gels before autoradiography. In *b*, membrane protein from the same samples was solubilized with 2% octyl glucoside, centrifuged to remove insoluble cytoskeletal aggregates and the soluble ^{32}P-proteins were immunoprecipitated with anti-transporter monoclonal antibody (lanes 1–3) or control monoclonal antibody (lanes 4–6). Lanes 1, 4, 4αPDD; lanes 2, 5, DMSO; lanes 3, 6, PMA. Preliminary experiments had established the presence of protein kinase C in human erythrocytes; although not detectable as a Ca^{2+}- and PS-stimulated kinase in red blood cell lysates, it was readily recognized following DEAE-cellulose separation of lysate proteins (not shown).

mediated phosphorylation of the glucose transporter. We are now investigating whether the phosphorylation of the erythrocyte transporter *in vivo* in response to PMA alters its activity and whether the stimulation of glucose uptake by PMA in other cell types is correlated with phosphorylation of the transporter *in vivo*. In addition to the possibility that such phosphorylation may directly affect the kinetic parameters of the transporter, in some cell types it may also lead to the redistribution of the transporter between the plasma membrane and intracellular membranes, such that a larger fraction of the transporter lies within the plasma membrane[15].

Evidence has been accumulating that epidermal growth factor and platelet-derived growth factor may lead to the activation of protein kinase C in intact cells[16–20]; this is often accompanied by an increase in phosphatidylinositol turnover, with the generation of diacylglycerol, an activator of the kinase[21]. Epidermal growth factor has also been shown to increase glucose uptake[22], while phorbol esters mimic the insulin-stimulated phosphorylation of the insulin receptor β-subunit on serine residues in IM-9 lymphocytes, suggesting that the kinase may be activated by insulin[23]. The present study suggests that the diverse effects of several hormones and phorbol esters on glucose transport may in part be linked through a common mechanism, phosphorylation of the glucose transporter by protein kinase C.

We thank Jeffrey Allard for the monoclonal antibodies; Esther Freiberg, Julie Colliton and Matthew Fitzgibbon for technical assitance; and Drs Joseph Avruch and Grant Fairbanks for helpful advice. The manuscript was ably prepared by Martha Chambers. This work was supported in part by NIH grants AM19270 and AM25336.

Unfashionable continua

Michael Berry

An Idiot's Fugitive Essays on Science: Methods, Criticism, Training, Circumstances.
By C. Truesdell.
Springer-Verlag 1985. Pp.654. DM 158, $45 20.

TO DESCRIBE Clifford Truesdell as a theoretician specializing in the mechanics of continuous distributions of matter would, although strictly correct, be misleading. It would fail to convey what this collection of reviews, prefaces and lectures abundantly does convey, the broad scale of Truesdell's researches in mechanics and its history and his concern for and lack of sympathy with the way science is practised today, all so intensely felt and expressed with such mastery of language that my attention was gripped and held.

It is important to study continuum mechanics because

Matter is commonly found in bodies consisting of materials. Analytical mechanics turned its back on this fact, creating the centrally useful but abstract concepts of the mass-point and the rigid body... "modern" physics likewise turns its back, since it concerns solely the small particles of matter, declining to face the problem of how a specimen made up of such particles will behave in the typical circumstances in which we meet it. Materials, nonetheless, continue to furnish the masses of matter we see and use from day to day: air, water, earth, flesh, wood, stone, steel, concrete, glass, rubber, All are *deformable*. A theory aiming to describe their mechanical behavior must take heed of their deformability and represent the general principles it obeys.

That theory is continuum mechanics. In renovating its foundations during recent decades, Truesdell and his colleagues have reversed the customary approach:

From the time of NEWTON until recently, many natural scientists considered the mass-point the fundamental quantity of nature, or at least of mechanics. They believed that matter was composed of many small particles obeying the laws of classical mechanics, and that, consequently, the behavior of gross matter could be predicted, in principle, to any desired accuracy, from a knowledge of the intermolecular forces Thus continuum mechanics appears as an approximate or at best secondary theory within classical mechanics. While this tradition clings on in physics teaching today, it defies reality.... The smallest units of matter are no longer believed to obey Newtonian mechanics.... In fact it is almost the rule that *Newtonian mechanics, while not appropriate to the corpuscles making up a body, agrees with experience when applied to the body as a whole...* . Only paedagogical custom has hindered the realization that *as a physical theory, continuum mechanics is better than mass-point mechanics.*

This has been an unfashionable view:

... "physics", by definition, is become exclusively the study of the structure of matter, while anyone who considers physical phenomena on a supermolecular scale is kicked aside as not being a "real" physicist. Often "real" physicists let it be known that all gross phenomena easily *could* be described and predicted perfectly well by structural theories; that, aside from the lack of "fundamental" (i.e structural) interest in all things concerning ordinary materials such as water, air, and wood, the blocks to a truly "physical" (i e. structural) treatment are "only mathematical".

It is curious that these same persons are often sympathetic to non-structural theories on the borders of physics. They do not suggest that a mathematical physiologist investigating models for behavior would do better to try to integrate the equations of motion for the elementary particles making up a rat

That was written in 1962. Although the point is still worth making, its thrust is blunted by the increasing readiness of physicists to apply theories where they are appropriate, with less fundamentalist prejudice against the macroscopic. One of several reasons for this is the renewed appreciation and extensive development of Poincaré's discovery of great complexity (including chaotic behaviour) in the solutions of the equations of mechanics, even when, as with mass-points, the equations themselves are simple. I would have liked to learn Truesdell's opinion of this new branch of mechanics, but was disappointed to find no mention of it.

Penetrating reviews of books about the Bernoullis, Euler and Newton illustrate Truesdell's insistence that criticisms should be based on detailed study of original sources rather than the writings of commentators. It is a pity that he fails to live up to these standards when attacking "applied catastrophe theory" as a misuse of mathematical modelling; apart from a brief quotation (without reference) from Zeeman, his remarks are all based on articles by other critics of the theory, and he fails to mention those cases (even in continuum mechanics) where the mathematics has found valid application.

More generally, Truesdell laments the decline of scholarship:

The world of "learning" has become a federation of hives of frightened bees, who so as to maintain their little waxen prisms sting all strangers, be they lions or mice or only bees from the next-door office.

He detests the way science has become a large-scale organized enterprise, that is:

.. science for, by, and of the demos, in a word, *plebiscience*. Plebiscience demands what POST has called "inevitable research: . research which is bound to yield *some* results"...Plebiscience is *big science*. Small science was done by a few great men. Big science calls for many little men.

Worse might be to come:

Plebiscience is an intermediate stage. The next and last is *prolescience* In it not only is all research inevitable research, but also only outcomes previously known and accepted are allowed The function of prolescience will be to confirm and comfort the proletariat in all that it will by then have been ordered to believe. Of course that will be mainly social science.

But after pages of splendid raging, with sour prejudice alternating with flashing insight, he is not without hope:

Even now, I think, there are men who live for science, men who strive to bake not witches' mess but giants' bread What they deliver may be as tedious to the plebs as a lute, but let us not forget that while a cure for cancer may raise the mean age of the population to ninety, a good lute may last to make beautiful music under the hands of men and women yet unborn.

Amen. □

Fifty years of the special senses

F. W. Campbell

Foundations of Sensory Science.
Edited by W. W. Dawson and J. M Enoch.
Springer-Verlag 1984. Pp.577. DM 288, $82.30.

THIS IS a collection of essays written by scientists who have accumulated age and wisdom and achieved success in their respective fields of neurosensory research The editors have encouraged them to clothe their accounts with personal details of how, and why, they chose a particular research direction. The result is a unique and fascinating volume, which it is unwise to start reading too late at night.

Today custom dictates that scientists report their findings in a cold impersonal style. Worse, most of us know that we often put our last experiment at the beginning of our papers, and the false-starts at the end, thereby giving a spurious impression of undue intelligence and rationality. As Edwin Land (of the Polaroid Corporation) once said, "An original idea only takes a few seconds cessation of stupidity". Many such seconds are brought to life in the book, in a relaxed manner which is much more illuminating than the formal prose of the scientific paper.

The 15 contributors are of international repute and they cover the entire range of special sense neurophysiology, including the relevant psychophysics.* Each describes their chosen problem as it was when they started as a young worker, and then unravels each twist of serendipity that put them back onto the successful track. The excitement and pleasure of the hunt are captured vividly, as are the dull and dispiriting periods which most researchers know all too well

The young, computer-orientated scientist of today may be surprised to learn that so many of the experiments described were done with simple, home-made apparatus; indeed, the most useful hobby seems to have been the building of short-wave radio and radar devices. However, it would be a mistake to conclude that research was straightforward in those times and, furthermore, that all the "easy" experiments have now been done. The picture that emerges is that the secret of research is to ask the right question at the right time and never to be discouraged by failure.

The authors are drawn from many different countries, and for almost all of them the Second World War had a dramatic impact on their workplace, personal life and future. Many of them were deflected into applied research, which they appeared to be equally good at, and in many cases their eventual field of study seems to have been determined simply by chance.

This elegant book provides a snapshot (with an exposure time of 50 years) of the foundations of the techniques which have enabled us to begin to probe the great, unsolved mystery of how animals sense their ambient environment. It is very well illustrated and included are most of the classical experiments up to the present time. The names index contains some 1,300 entries, and a newcomer to work on any of the special-senses would do well to begin here where they will be directed to the relevant seminal research. Moreover, the book brings together the sensory physiology of a very wide variety of species. One of the best starting points is Fig. 1 on page 382, where an illustration of the bombykol receptor cell of the moth will immediately lead you into the pheromone quest.

The editors, W. W. Dawson and J. M. Enoch, must have had a difficult time blending together the writings of such a variety of personalities. This they have done with an affection for experimental neurosensory science which runs through every page. □

More of the unseen Universe

Reuven Ramaty

Gamma Ray Astronomy.
By Rodney Hillier.
Oxford University Press: 1984. Pp. 202. £19, $29.95.

IN THIS rather brief volume, Dr Hillier has attempted to present the theoretical concepts, the principal observational results and the detection techniques of gamma-ray astronomy. After an introductory chapter and an account of astrophysical gamma-ray production, five chapters are devoted to detection techniques and four to observations. Thus most of the important aspects of gamma-ray astronomy are covered, but to me the book seems to lack the depth that would be expected from a modern work on the subject. Moreover many of the topics covered have been previously treated in Stecker's *Cosmic Gamma Rays*, published in 1971, and in Chupp's *Gamma Ray Astronomy* of 1976.

The book is not entirely up to date and contains some errors. The Crab nebula is powered by the Crab pulsar and not by ^{249}Cf (p.11). The energies of the line photons resulting from positron annihilation are equal to the electron rest mass energy and not to half of this energy (p.12). And the lifetime of the 4.43 MeV level in ^{12}C is less than 5×10^{-14} s, and not $\sim10^{-12}$ s (p.6) This difference has important astrophysical consequences regarding the width of the line, as was pointed out by Lingenfelter and Ramaty in connection with gamma-ray line emission from interstellar grains (*Astrophys. J.* **211**, L19; 1977).

There are also some omissions and some topics are covered rather sketchily, for example optical flashes from gamma-ray bursters. Even though optical observations technically do not belong to the realm of gamma-ray astronomy, Schaefer's discovery (*Nature* **294**, 722; 1981) of a historical optical flash in the error box of a gamma-ray burster has been one of the most important observational advances in this area in the past few years. As such, it should have been included in the book. Similarly, because of their close relationship to gamma-ray observations, neutron observations from solar flares (Chupp *et al. Astrophys. J.* **263**, L95; 1982) should also have been mentioned. Another topic not fully covered is the time variability of the 0.511 MeV annihilation line from the direction of the galactic centre. This variability, first reported by Riegler *et al. (Astrophys. J.* **248**, L13; 1981) effectively excludes multiple or extended positron sources, for example pulsars, supernovae, primordial black holes or cosmic rays. The reference to the work of Paciesas *et al.* (p.161) relates only to the variability of the continuum emission from the direction of the galactic centre, but not to that of the annihilation line.

Overall, this is a book to which students wishing to become acquainted with the subject can be directed (though some mathematical ability is needed to get the best out of it). On the other hand, because of the failings outlined above, I cannot recommend Hillier's *Gamma Ray Astronomy* to advanced graduate students or active researchers. □

Reuven Ramaty is at the Goddard Space Flight Center, Greenbelt, Maryland.

Doing the rounds of the Solar System

Carl D. Murray

Rings: Discoveries from Galileo to Voyager.
By James Elliot and Richard Kerr
MIT Press·1985. Pp.209.
$17.50, £19.50.

OBSERVATIONS of the occultation of star SOA 158687 by the planet Uranus on 10 March, 1977, were intended to provide information on the shape and atmosphere of Uranus An unexpected bonus for Jim Elliot and his team in the Kuiper Airborne Observatory was the first discovery of a ring system since the time of Galileo After more occultations, the spectacular successes of the Pioneer and Voyager spacecraft and the increased use of charge coupled devices (CCDs), astronomers now have the luxury of studying planetary rings on a comparative basis.

Even to document the recent discoveries and theories is a difficult task after such an influx of ground-based and spacecraft results. But the authors of this book do not merely present the observations together with the latest well-polished theories, they also treat the reader to a revealing and honest portrayal of scientific discovery, complete with rejected grant applications, rivalry and occasional good luck

In particular, the account of the spacecraft flybys captures the unique atmosphere of "instant science", when making discoveries "is just a matter of who's around". Explaining them can take a little longer. Theorists have had to turn their attention to such phenomena as narrow rings, eccentric rings, multiple rings and "spokes". The book relates how, during the Voyager 1 encounter with Saturn, some of the best theorists were unable to explain the "braided" appearance of Saturn's F-ring Although there were doubts that gravitational forces alone could account for such a feature, one of the faithful remarked, "Don't worry about Newton's equations, most people don't realize how many solutions they have" Current theories of the F-ring have shown that his faith in gravity was not misplaced.

Accounting for some features can lead to more fundamental problems Studies of satellite–ring interactions and the identification of spiral density waves have provided an explanation for most of the structure in Saturn's A-ring. However, the same studies reveal the possibility that unless some locking mechanism can be found we may have to come to terms with the fact that the rings are relatively short-lived phenomena.

The combination of first-hand experience and good journalism has resulted in an immensely readable account of how ring studies have evolved over the past three centuries Glimpses of the personalities involved and clear explanations of the various physical processes and ring theories help to convey the excitement of science This golden age of discovery is not over In January 1986 we can expect images of the Uranian rings from Voyager 2 Before the end of the decade we will have further information on the peculiar rings or arcs of material around Neptune and a look at Jupiter's ring from the Galileo spacecraft. There will be more discoveries, more puzzled astronomers, more theories and, we must hope, an equally fascinating sequel to this splendid book □

Levels of dispute

Paul Hoyningen-Huene

Science and Values: The Aims of Science and Their Role in Scientific Debate.
By Larry Laudan
University of California Press·1984.
Pp.149. $15, £14.25.

SCIENCE, viewed as a social enterprise, has two complementary features: the formation of agreement from disagreement and the formation of disagreement from agreement. The task of explaining these features was made prominent more than 20 years ago by Thomas S. Kuhn in his *Structure of Scientific Revolutions*. Laudan takes up the subject once more, thus putting himself in competition with Kuhn and many other writers. Before addressing the resulting quarrels, we should look at the model that Laudan proposes.

Laudan distinguishes three levels of scientific commitment on which agreement or disagreement occurs: a "factual level", concerning claims about the world, a "methodological level", concerning claims about the correct way of doing science, and an "axiological level", concerning the basic cognitive aims of science (that is, those properties of theories that are constitutive of *good* theories). Traditionally, the interaction between these levels is seen as follows: disagreement on the factual level can be rationally resolved by recourse to the methodological level, and disagreement on the methodological level by recourse to the axiological level. The second of these steps is possible since methodological rules are instruments for realizing cognitive goals. The obvious difficulty which this hierarchical dependence of levels leaves unresolved is that disagreement on the axiological level cannot be eliminated.

Laudan adds more interactions to the traditional hierarchical dependence of the levels, resulting in what he calls the "reticulated model". In this model, the methodological level is also influenced by the factual level. Scientific methods can and must, he says, be judged also with respect to the factual level. what is already known about a subject matter obviously influences the choice of subsequent scientific methods. Second, the axiological level is connected to the other levels by feedback loops that sometimes allow for rational resolution of axiological disagreement. Explicit cognitive values — value statements — may, according to Laudan, rationally be criticized for being "utopian", that is for being incapable of application, or for not being consonant with shared exemplary scientific work. (At this point, however, Laudan appears to confound explicit value *declarations* with values displayed in actual scientific *practice*) The interdependence of the different levels in the reticulated model permits rational transitions between many of the eight combinatorially possible states of three-level agreement–disagreement.

Laudan's development of the model is accompanied by attacks on other writers in the field. Correspondingly, he declares his book to be a contribution to the "decanonization of a discipline's patron saints" (xiii), and his principal target throughout is T.S. Kuhn. But the creature decanonized by Laudan is largely a product of his own imagination For example, a central sin that Laudan identifies in Kuhn's work is what he calls "the covariance fallacy", the assertion of a rigid bond between changes on the factual and on the axiological level (43ff.) But Kuhn, in an article that Laudan repeatedly cites, has described at length a very different sort of association, one that invokes just the sort of delayed feedback loop that Laudan takes to be his own. Elsewhere, documenting Kuhn's distrust of rationality, Laudan attributes to him the view "that it was *perfectly reasonable* for Priestley to hold onto phlogiston theory" (pp.72–73, my italics). But what Kuhn said in the relevant passage is the reverse: "the historian can always find men — Priestley, for instance — who were *unreasonable* to resist for as long as they did" (*Structure*, p 159, my italics). These examples stand for a host of others. Scholarly debate should not be conducted in this way. □

Paul Hoyningen-Huene, currently a Visiting Scholar at the Massachusetts Institute of Technology, is a Lecturer in Philosophy of Science at the Universities of Bern and Zürich

●The most recent volume to appear in Pergamon's *Key Environments* series is *Antarctica*, edited by W N Bonner and D W H Walton. Price is £14 95, $23.95 For review of the first three volumes see *Nature* 312, 205 (1984)

CALL FOR PAPERS

new journal for the earth sciences

LONGMAN
in association with the
Quaternary Research Association
are pleased to announce an important new journal in the Earth Sciences.

JOURNAL OF QUATERNARY SCIENCE

edited by Dr J. J. Lowe, City of London Polytechnic, on behalf of the Quaternary Research Association.

The Journal of Quaternary Science will publish original papers on all aspects of Quaternary Research, the branch of the earth sciences concerned with the last two million years of earth history. The Journal will be international and interdisciplinary and contributions are now being sought from researchers in appropriate fields, including geology, geomorphology, archaeology, botany, climatology, geophysics, glaciology, oceanography, palaeontology, soil science and zoology. A distinguished international editorial board is in the process of formation. A style guide is in preparation but prospective contributions should follow standard scientific conventions for the time being.

The Journal will be launched in April 1986; Two 96-page issues per year Annual subscription £35· $70 US

Editorial enquiries and correspondence Dr J J Lowe, Department of Geography, City of London Polytechnic, Calcutta House, Old Castle Street, London E1 7NT, UK

Subscription enquiries Clive Weatherley, University and Further Education Division, Longman Group Ltd, Longman House, Burnt Mill, Harlow, Essex CM20 2JE, UK

Harpenden, Herts AL5 2JQ

HIGHER SCIENTIFIC OFFICER

required by the Insecticides & Fungicides Department to work on techniques to delay insecticide resistance in the white fly. The post is funded by Ciba-Geigy AG for a period of two years.

Qualifications: First or Upper Second Class honours degree in either Entomology, Agricultural Science or Applied Biology with at least two years relevant post-graduate experience. A PhD would be an advantage.

Appointment in the grade of Higher Scientific Officer on scale £7,788—£10,541. Non-contributory superannuation.

Applications giving full cv, the names of two referees and quoting Ref: 596 should be sent as soon as possible to The Secretary. Closing date 19 July 1985. Further particulars on request. (6948)A

THE UNIVERSITY OF LEEDS
FACULTY OF MEDICINE

MANAGER, LABORATORY ANIMAL SERVICES

Applications are invited for the above post available from 1 October 1985. Applicants should have not less than 12 years' experience in animal technology and appropriate management experience. The successful candidate will be responsible for the provision of laboratory animal services to the departments of the Faculty of Medicine. The service has a total technical staff of 26 and is responsible for a wide range of laboratory animals.

Salary on Grade II of the salary for Other Related Staff (£11,675 — £14,925) (under review).

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference no. 93/9.

Closing date for applications 24 July 1985. (6920)A

UNIVERSITY COLLEGE
CORK

RESEARCH POSITIONS IN MICROBIOLOGY/ BIOTECHNOLOGY

POSTDOCTORAL RESEARCH ASSOCIATES

(2) to work on projects involving molecular genetics of plant-microbial interactions —

(A) to investigate genes involved in carbon metabolism in Rhizobium (Genetic Engineering);
(B) to investigate the regulation of carbon metabolism in Rhizobium and plant growth promoting Pseudomonas spp. (biochemical-genetics/physiology).

Positions are available from 1 July 1985 and salary will be in the range IR£8,596-IR£11,173 (less PRSI contribution) according to experience.

Applications including a C V. and the names of two referees should be sent as soon as possible to Dr F. O'Gara, Microbiology Department, University College, Cork, Ireland, from whom further particulars are available. (6903)A

AGRACETUS
BIOTECHNOLOGY

Scientist — Molecular Biology

The Agracetus plant genetic engineering group has a vacancy for a scientist with experience in eukaryotic molecular biology. Applicants should have demonstrated competence in one or more aspects of recombinant technology including construction of genomic libraries, cDNA cloning, or expression of foreign genes in eukaryotic cells. The scientist chosen for this position will join a growing interdisciplinary research team working toward the genetic improvement of major crops.

Agracetus has evolved from Cetus Madison Corporation as a joint venture initiated by W.R. Grace & Co. and Cetus Corporation. The partnership combines the research strengths and technology of Cetus with the business experience and success of the Grace Agrichemicals Group.

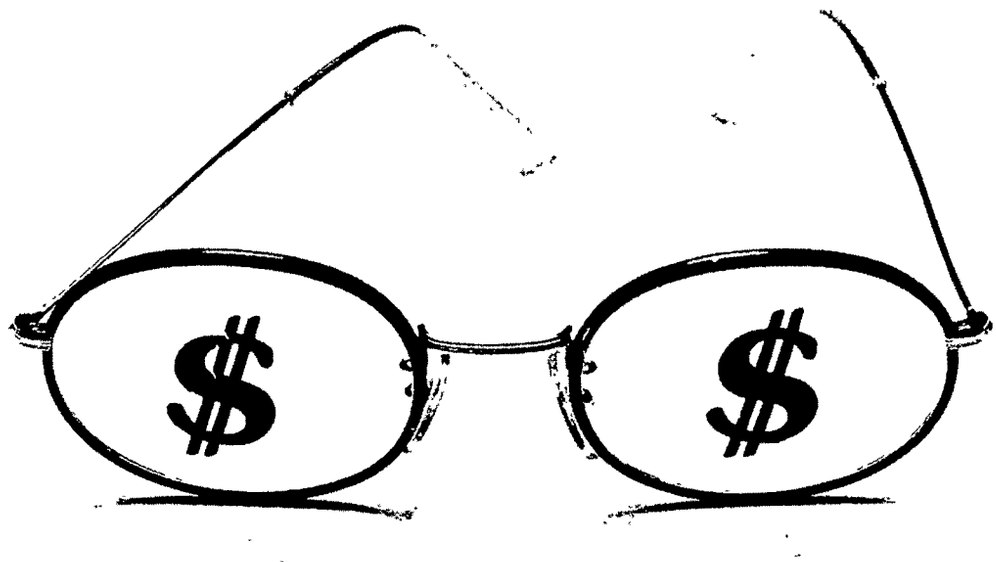
Agracetus is an industry leader in applying the techniques of biotechnology to agriculture. The location of the research complex near the University of Wisconsin in Madison, provides an ideal setting for both career and lifestyle enhancement.

We offer a competitive salary, a comprehensive benefits package, and advancement opportunity

Send a detailed curriculum vitae, a list of publications, and three letters of recommendation directly to **Dr. Winston J. Brill, Agracetus, 8520 University Green, Middleton, WI 53562.** We are an equal opportunity employer

(NW1902)A

Agracetus



Recombinant DNA specialist post-doctoral level

If your sights are aimed at the field of genetic engineering focus in on a laboratory where sophisticated technology and the latest ideas go hand in hand with the strength of France's n° 1 chemical and pharmaceutical group-which also happens to be among the top 10 in the world. The Rhône Poulenc Group provides Génétıca with an industrial scale structure for research, application and sales, thus giving Génética every chance to produce broad ranging applications and all of the resulting financial benefits. Ten years ago, the field of genetic engineering didn't even exist. Our main projects performed until 1984 Génética has successfully cloned and expressed the gene of a pharmaceutical enzyme, the numerous genes – approximately 20 – of the biosynthetic route to the vitamine B 12, an important drug and food additive, and the gene of two medically valuable human proteins.

If you would like to broaden your professional horizons, join a laboratory that really counts in this field. You will find your working environment, just thirty minutes from the heart of Paris, both pleasant and stimulating.

Please send your application (résumé) to GENETICA, 160 quai de Polangis, 94340 Joinville-le-Pont, Paris - FRANCE.

média-system

France, too, needs researchers who want to put their skills to use.

GENETICA VOIT GRAND DANS LE DOMAINE DE L'INFINIMENT PETIT.

Neuroscientists in Research

The expansion of our Industrial Division's Research facilities in Nottingham has created the following key opportunities for scientists to join our Mental Illness Research Group.

Section Leader

A pharmacologist, biochemist or biologist to head a section primarily concerned with the research and development of anti-depressants. You should have considerable relevant post-doctoral experience, preferably gained in a pharmaceutical company or in an industrial-collaborative environment coupled with substantial experience of scientific group management

Team Leader

A neuroscientist to help in the building up of a team to research into new antipsychotic drugs, several years post-doctoral experience, not necessarily gained in the pharmaceutical industry, is essential.

Research Scientist

A recently qualified post-doctoral scientist with training in neuropharmacology to participate in a programme of work involving monoamine metabolism and directed to the evaluation of new drugs acting on the central nervous system.

The competitive salaries offered for these new and responsible positions will be related to experience. An excellent benefit package includes profit sharing bonus, staff purchase privileges and a generous relocation allowance, where applicable, to assist with moving to this attractive part of the country.

Please write with full career details, including publications to: Mr. T. W. Flower, Employment Manager (Technical), The Boots Company PLC, Station Street, Nottingham NG2 3AA. (6951)A

The Boots Company PLC

UNIVERSITY OF NATAL
Department of Biochemistry
PIETERMARITZBURG

Applications are invited from suitably qualified persons regardless of sex, religion, race, colour or national origin for appointment to the post of:

LECTURER

The appointee will be expected to participate at all levels in the teaching programme including his/her own specialisation. In addition the appointee will be encouraged to become involved in active research. It is essential therefore that applicants have an interest in both teaching and research.

The minimum qualification for the post is a M.Sc. degree.

The appointment carries an attractive salary package, details of which are obtainable from the Staffing Section on request (telephone 0331-63320). The salary offered will be determined according to the qaulifications and/or experience of the successful applicant.

Application forms, further particulars of the post, and conditions of service, are obtainable from the Registrar, University of Natal, P.O. Box 375, Pietermaritzburg, 3200, with whom applications on the prescribed form must be lodged no later than 31 July 1985, quoting reference PMB 43/85.

Application forms for overseas applicants are available from the Secretary, South African Universities Office, Chichester House, 278 High Holborn, London WC1V 7HE. (W1968)A

BIBRA

DIRECTOR

The British Industrial Biological Research Association wishes to appoint a Director, as Chief Executive, in succession to Professor D.M. Conning, recently appointed as Director-General of the British Nutrition Foundation.

Founded in 1960 to carry out toxicological research, the Association currently is funded mainly by Government and the food and allied industries. The Association conducts multi-disciplinary research to develop methods of safety evaluation, supply information and prepare toxicological assessments for use by industry, government departments and regulatory authorities internationally.

Candidates should be internationally known experimental scientists with the capacity to manage 150 staff in laboratories at Carshalton, Surrey.

This important post will be filled by someone with the stature to give leadership in the generation of science to resolve current problems, including risk assessment and the extrapolation of experimental data to man, and who will broaden the international role of the Association.

Applications, which will be treated in the strictest confidence, should be addressed to the Chairman of Council, Mr E.A. Flack at Grindsted Products Limited, Northern Way, Bury St. Edmunds, Suffolk IP32 6NP, England. (6914)A

OXFORD POLYTECHNIC
DEPARTMENT OF BIOLOGY
POSTGRADUATE RESEARCH IN RECOMBINANT DNA TECHNOLOGY

A Researcher A post (£5,181 — £7,176 per annum) will be available from 1 September 1985 for research training, leading to MPhil/PhD (CNAA), in the construction and use of novel transposons for mutagenesis in gram negative bacteria under the supervision of Dr M Woodward.

This Researcher A post will involve teaching duties on undergraduate courses in biochemistry and microbiology.

Further details of the project and of research in the Department are available from the Postgraduate Tutor.

Applicants should possess a good honours degree in an appropriate subject. They should provide a curriculum vitae including full details of any experience relevant to the project and the names of two academic referees.

Applications should be sent to: The Postgraduate Tutor, Department of Biology, Oxford Polytechnic, Heading Oxford OX3 0BP.

CLOSINF DATE 12th July 1985.

An Equal Opportunities Employer. (6967)A

DEPARTMENT OF RESEARCH AND SPECIALIST SERVICES

MINISTRY OF AGRICULTURE

ZIMBABWE

As part of its plans for strengthening the research and extension services in agriculture, the Department of Research and Specialist Services requires scientists and technologists to work on three year assignments in the positions indicated below.

Since independence, the high level of services provided by the Department to the established commercial farmers has been maintained but special attention is being given to the needs of the small farmers and the resettlement and communal areas. The Department has responsibilities for the furtherance of the welfare and technical progress of Zimbabwe agriculture, for conducting research in agricultural science and crop and livestock production and for the provision of services to the agricultural industry. It is also entrusted with regulatory services. The Department employs a staff of over 350 professional and technical officers and some 1500 supporting personnel.

CROP RESEARCH DIVISION

— **UTILITY PLANT BREEDER for CEREALS**
(Winter Wheat, Barley, Millets & Sorghum)

— **UTILITY PLANT BREEDER for OILSEEDS and FOOD LEGUMES**
(Groundnuts, sunflower & pulses)

— **IRRIGATION AGRONOMIST for LOW COST IRRIGATION SYSTEMS**
(To establish minimum requirements for a variety of crops, particularly wheat, cotton, vegetables and a wide range of tree crops)

LIVESTOCK AND PASTURES DIVISION

— **PLANT BREEDER FOR GRASSES**
(Investigations to include Rhodes grass strains and potential crosses with giant strains aimed at combining high production with resistance to root-knot nematode, and consideration of possible avenues for pasture legume breeding)

— **RANGE ECOLOGIST**
(To design trials for reclamation of degraded sandweld rangeland in communal areas)

— **RUMINANT NUTRITIONIST**
(To design research trials on nutrition of cattle and small livestock and review current research into fattening and intensified production systems)

— **MEAT TECHNOLOGIST**
(To develop training programmes for meat graders)

RESEARCH SERVICES DIVISION

— **SOIL PHYSICIST**
(To provide analytical service in soil physical properties, support soil survey staff by research on soil suitability for irrigation and other development and in rapid field assessment of permeability and moisture release)

— **SOIL MICROBIOLOGIST**
(To conduct research on microbiological aspects of rhizobial innoculants and coordinate work of the Inoculant Factory and Microbiological Laboratory)

— **PLANT ECOLOGIST**
(To provide vegetation inputs for natural resources survey of communal lands, involving aerial photograph & satellite imagery interpretation, computerised analysis of vegetation data and sampling techniques and to conduct research into use of vegetation in reclamation of degraded lands)

— **SENIOR AGRONOMIST/PHYSIOLOGIST**
(To devise technical packages for communal area research trials covering appropriate varieties, populations and fertiliser requirements for maize, field beans, sunflower, groundnuts, sorghum, soyabeans, pearl millet and cowpeas and an agronomy programme covering proper tillage methods, moisture conservation and resistance to waterstress of major field crops)

The training of local staff through in-service lecture courses, practical demonstrations and examinations, on the job training and supervision of post graduates and diplomate research studies is an essential and integral part of all assignments.

Applicants should have appropriate academic qualifications and must be able to demonstrate a high level of achievement in their disciplines as well as their capability in the field of training. At least five years research experience in tropical agriculture is required.

Remuneration package includes US dollar salaries and allowances net of local tax, furnished housing, annual leave passages and assistance with education expenses. These appointments are funded by the World Bank and successful applicants will be contracted to AMEX Consultancy Ltd, who have been retained by the Government of Zimbabwe to support this important programme.

Applications in writing with full CV's and references to AMEX Consultancy Ltd, 28 Old Church Street, London SW3 5BY.

ADVANCED DRUG DELIVERY RESEARCH

Horsham, West Sussex

Ciba-Geigy Pharmaceuticals has established in Horsham a major new research unit dedicated to the discovery and exploitation of new concepts for drug delivery. The unit provides exceptional opportunities for imaginative and highly motivated scientists to carry out original research in a stimulating and challenging multi-disciplinary environment.

Applications are invited for the position of:

SCIENTIST

To be responsible for, and to operate a flow cytometer within a broad range of applications in the areas of cell biology and molecular biology.

The successful candidate will be expected to develop and maintain expertise in the technique of flow cytometry, and to interact with the members of the Unit in the development of experimental programmes.

Suitable candidates should have an interest in modern analytical and instrumental techniques, a basic knowledge of computing, and a sound background knowledge of immunology and cell biology.

Practical experience in the use of flow cytometry, although not essential, would be an advantage.

The salary and benefits package for this position is very attractive, and will include relocation expenses where appropriate.

Please send a letter of application, together with a full c.v. to:-

Miss S. J. Byrne, Personnel Officer, Ciba-Geigy Pharmaceuticals, Wimblehurst Road, Horsham, West Sussex RH12 4AB.

(6981)A

CIBA–GEIGY

ANIMAL NUTRITIONISTS (2) VACANCY INT/001/85

The International Livestock Centre for Africa (ILCA) seeks two Animal Nutritionists to be based at Headquarters in Addis Ababa. One will be required to participate in ongoing research programmes on the evaluation of crop residues and the nutrition of draught animals. The other, who will be expected to travel extensively in various parts of Africa, will be concerned with an ongoing programme in the nutrition of trypanotolerant livestock and those exposed to trypanosomiasis.

Successful applicants will have PhD degrees in ruminant nutrition as well as several years experience in the field. Knowledge of French would be a considerable advantage for applicants for both posts.

Salary and related benefits will be in line with comparable international organisations.

Applicants should airmail personal history and names of three referees. Applications citing the above reference number should arrive to the Head of the Personnel Department, International Livestock Centre for Africa, P.O. Box 5689, Addis Ababa, Ethiopia before August 31, 1985.

(W1982)A

MEDICAL RESEARCH COUNCIL

National Institute for Medical Research

VIROLOGY DIVISION

Applications are invited for a postdoctoral position in initiate an independent programme to study microtubule mechanisms in the spatial organisation of cells. The candidates should have several years experience in relevant areas of cell biology, and be interested in collaborating with scientists with related research programmes. The Institute offers excellent facilities and opportunities for collaboration in this area at both molecular and cellular levels.

The appointment will be for five years and the salary will be at an appropriate point on the scales for University non-clinical academic staff, plus £1,233 London allowance and superannuation provision.

Applications, giving full curriculum vitae, research experience and the names of two professional references, should be sent to the Director, National Institute for Medical Research, Mill Hill, NW7 1AA before 26th July 1985, quoting ref: V/7/M. (6950)A

ASSOCIATE SCIENTIST

Applications are being accepted for the position of Associate Scientist for a PhD in Immunology and at least 3 years of experience. The candidates selected will become an integral part of the research team involved with the study of cell-mediated immunity and viral diseases. The candidate should also have extensive knowledge in the study of coranaviruses, orthomyxoviruses, and cellular immunology.

Salary range — $20 to $23,000 per year.

Forward résumé to: Patricia Menei, Personnel Dept., THE WISTAR INSTITUTE, 36th & Spruce Sts., Philadelphia, PA 19104. EOE. (NW1912)A

POSTDOCTORAL POSITION

available in a clinical immunology laboratory to study the ontogeny of the immune response with special emphasis on the relationship between differentiation and cancer. Minimum qualifications are a Ph.D. degree with a background in either immunology, biochemistry, cell or molecular biology. Funding starts 1 Sept. 1985.

Please send résumé, statement of research interests, and names of three references to: Dr. Florence Hofman, Department of Pathology, University of Southern California, Los Angeles, CA. 90033.

(NW1917)A

Microbiologists

Antibacterial Chemotherapy

The Wellcome Research Laboratories is the main centre for the research activities of The Wellcome Foundation Ltd., a major group of pharmaceutical and chemical companies with headquarters in the UK and a turnover close to £800m.

The major objective of the Department of Biochemical Parasitology is the discovery and development of novel drugs for the microbial and parasitic diseases of man, including tropical diseases.

We now have two challenging opportunities for experienced Ph.D. Microbiologists to join a multidisciplinary team committed to the rational design and development of new antibacterial agents.

Senior Microbiologist £11,400–£15,800

You will play a key role in the overall development and operation of the evaluative component of the team's effort and will also undertake personal research work pertinent to that area. Five years' post-doctoral experience in antibacterial chemotherapy, preferably in an industrial or hospital environment, is essential for this appointment. The ability to integrate effectively with scientists at all levels and from other disciplines will also be a prime requirement. Ref: WRL/347.

Microbiologist £9,400–£12,500

You will be one of a small group of microbiologists engaged in the evaluation of known and newly designed antibacterial agents at the whole organism level, both *in vitro* and *in vivo*. Flair for innovation, especially in the development of novel assays, plus 1 or 2 years' post-doctoral experience are essential for this position. This appointment will initially be for one year in the first instance, with probable renewal for at least 2 more years. There may be opportunity for transfer to an established position in the longer term. Ref: WRL/348.

We offer an attractive starting salary, dependant on experience, and our excellent benefits package includes five week's holiday, pension fund, sick pay scheme, subsidised restaurant and assistance with relocation expenses where appropriate.

Please write with full details, quoting the appropriate reference, to Dr H D Avshu, Personnel Officer, The Wellcome Research Laboratories, Langley Court, Beckenham, Kent BR3 3BS. (6983)A

An equal opportunity employer

(NW1896)A

Structural Molecular Biologist

BROOKHAVEN NATIONAL LABORATORY

A staff position is open in the Biology Department for a structural molecular biologist with experience in the field of small angle X-ray scattering. This is an opportunity for a scientist to develop an independent program at the small angle scattering station of the National Synchrotron Light Source (NSLS). The scientist will also be responsible for the operation and development of the small angle scattering facility.

Candidates should submit a curriculum vitae that includes a list of publications and the names of three references, together with a statement of research interests, to: H.Z. Kondratuk, Biology Department, Brookhaven National Laboratory, Associated Universities, Inc., Upton, Long Island, NY 11973. Equal Opportunity Employer m/f.

BROOKHAVEN NATIONAL LABORATORY
ASSOCIATED UNIVERSITIES INC

(NW1904)A

The European Molecular Biology Laboratory, an international research institute situated in Heidelberg, West Germany, invites applicants for the following vacancy at the Laboratory's Outstation at the Deutsches Elektronensynchrotron (DESY) site in Hamburg

BIOCHEMISTRY LABORATORY ASSISTANT

The Outstation at the storage ring DORIS is dedicated to the use of synchrotron radiation in biological structure research The successful candidate will be responsible for maintaining the biochemical facilities used by visiting groups carrying out research projects at the Oustation for limited periods of time Besides this, there is an opportunity to participate in a limited in-house project on assembly properties of components of the cytoskeleton or on the structure of chromatin

Applicants should have an appropriate degree and advanced technical skills A knowledge of more than one of the official languages of the Laboratory (English, French, German) would be an asset

The net monthly salary will be between DM 2770, - and DM 3170, - Certain allowances are payable in addition, depending on personal circumstances An initial contract of 3 years' duration, which can be renewed, will be offered

Please write briefly for an application form, quoting reference 85/16 to

INTERNATIONAL CROPS RESEARCH INSTITUTE FOR THE SEMI-ARID TROPICS (ICRISAT) near Hyderabad, India

invites applications for

PRINCIPAL PLANT PATHOLOGIST (PULSES)

To lead the pulses (chickpea and pigeonpea) pathology team in the development, execution, and reporting of results of plant disease research projects that meet the needs of the interdisciplinary, international Pulses Improvement Program, and participate in activities that contribute to the achievement of the Institute's research and training objectives. The major emphasis for disease control research is on the identification and utilization of stable and durable host plant resistance. A Ph.D. in Plant Pathology, and at least 7 years relevant research experience are required. Proficiency in English and a willingness to travel frequently in the chickpea — and pigeonpea — growing regions of the world are essential. Tropical agricultural research experience is desirable. The appointee will be based at the ICRISAT Center, Patancheru, 30 km NW of Hyderabad. Hyderabad offers good access by air to international airports and has good living conditions, recreational and medical facilities. Educational facilities exist for children to the age of eleven or twelve.

Salary at principal staff level, according to qualifications and experience. Send résumé, including present salary level, and names of three referees, via air mail, to:

Director General, ICRISAT Patancheru P.O., A.P. 502, 324, India

within 60 days from the date of advertisement.

(W1967)A

Department of Agriculture and Rural Affairs

ANIMAL RESEARCH INSTITUTE, WERRIBEE, VICTORIA, AUSTRALIA 3030

AGRICULTURAL RESEARCH OFFICERS
(3 years) Three Positions

Salary Range: Science-3, $30,598 — $30,755 (2 positions)
Science-2, $26,697 — $29,167 (1 position)

We are seeking to appoint 3 people to undertake research into the management of livestock production systems using systems research techniques.

(1) SCIENCE-2, Position No. Ex.1039
(2) SCIENCE-3, Position No. Ex.1040

(Appointment is based on qualifications and experience)

More specifically, the successful applicants for these two positions will be required to develop computer programs for use by extension officers in formulating farm management decisions for either prime lamb or beef producers.

(3) SCIENCE-3, Position No. Ex.1041

More specifically, the successful applicant for this position will be required to identify opportunities for improving the profitability of wool production.

Applicants for all positions must have completed a degree or diploma in Science, Agricultural Science or an equivalent qualification.

It is desirable that applicants have an extensive knowledge of computing systems and simulation modelling; broad knowledge of plant and animal physiology and farm management practices; experience and expertise in computer systems and simulation studies, preferably in relation to agriculture, knowledge of Victorian or other prime lamb or beef production systems would be an advantage for positions nos. Ex.1039 and 1040; knowledge of Victorian or other wool production systems would be an advantage for position no. Ex.1041.

The successful applicants will be joining a small experienced team based at Werribee, with Statewide responsibilities for implementing the program

Employment in these positions is initially authorised for 12 months but is expected to be extended to 3 years.

Written applications are invited from men and women quoting the relevant position nos. and giving details of qualifications and experience and a contact telephone number. Applications should be forwarded to the Director of Personnel, Department of Agriculture and Rural Affairs, 166 Wellington Parade, East Melbourne, Victoria 3002, Australia, by the close of business on July 12, 1985.

For further information contact Dr. D. A. White on (03) 7411300.

(W1979)A

NEUROENDOCRINOLOGIST
Department of Physiology
QUEEN'S UNIVERSITY

A vacancy exists for an experienced neuroendocrinologist. The preferred applicant should have the Ph D and/or the M.D degree, several years teaching experience and a record of independent research of high quality. The applicant will be expected to lead an active research program and to participate in undergraduate and graduate teaching. The facilities for research are outstanding and the appointment is a regular one under tenure regulations. The appointment will be made at a level appropriate to the candidate's qualifications

Applications are encouraged from candidates of either sex. Applicants should submit a curriculum vitae, a brief statement of their research interests and objectives, selected reprints, and the names of three referees from whom a confidential assessment of research and teaching abilities may be obtained to: Dr. V. C. Abrahams, Department of Physiology, Queen's University, Kingston, Ontario, Canada K7L 3N6. (Second Advertisement).

THE AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited from suitably qualified men and women for appointment to the following positions:

Research School of Biological Sciences

DEPARTMENT OF DEVELOPMENTAL BIOLOGY
POSTDOCTORAL FELLOW GRADE I/RESEARCH FELLOW

A post is available from 1 January 1986 for studies of the nature and function of cytoskeletal components of plant cells. Experience of techniques of protein biochemistry is required Postdoctoral experience is a prerequisite for appointment as Research Fellow. The appointee will be expected to develop independent and/or collaborative research programmes with other members of the Department who are using immunological and microscopical techniques to study the plant cell cytoskeleton. Knowledge of plant systems is desirable but applications from animal cell biologists will be welcome

Closing Date **1 September 1985** Ref: BS 6 6.1

DEPARTMENT OF NEUROBIOLOGY
POSTDOCTORAL FELLOW GRADE I/RESEARCH FELLOW

A position is available from late 1985 for analysis of the invertebrate nervous system by any of the modern single-cell techniques such as microelectrode recording, monoclonal techniques, neurochemistry or on-line data analysis of neuron activity. The appointee will be expected to develop independent and/or collaborative research programmes with other members of the Department. Two positions may be available.

Closing date. **1 August 1985** Ref: BS 6 6.2

VIRUS ECOLOGY RESEARCH GROUP
POSTDOCTORAL FELLOW GRADE I/RESEARCH FELLOW

A position is available from 1 January 1986 for studies of the molecular evolution of viruses. Experience of techniques of protein and nucleic acid biochemistry, especially nucleic acid sequencing, is required. Experience with viruses would be helpful but is not essential. The appointee will be expected to develop a collaborative research programme with other members of the Group, this might involve studies of viruses from one or other of the poxvirus, orthomyxovirus, tymovirus or tobamavirus groups.

Closing date. **1 September 1985** Ref: BS 6.6 3

CONDITIONS OF APPOINTMENT: Salary will be in accordance with qualifications and experience within the range. Research Fellow $A26,236-$34,467 p.a.; Postdoctoral Fellow Grade I $A22,614-$25,905 p.a. Current exchange rate $A1=UK 50p

Appointment, unless otherwise stated, will be: Senior Research Fellow/Research Fellow normally up to three years with the possibility of extension to maximum of five years; Postdoctoral Fellow normally two years, with the possibility of extension to maximum of three years.

Grants are provided towards travel and removal, though special conditions may apply to persons appointed to externally funded positions Assistance towards housing is given to an appointee from outside Canberra. Eligible appointees will be required to join the Superannuation Scheme for Australian Universities. Maternity leave is available. The University reserves the right not to make an appointment or to make an appointment by invitation at any time. Applicants should quote the advertisement reference when requesting further particulars and when submitting applications, which should be sent to the Acting Registrar of the University, GPO Box 4, Canberra, ACT 2601, Australia. Further information also available from the Secretary General, Association of Commonwealth Universities (Appts.), 36 Gordon Square, London WC1H 0PF

THE UNIVERSITY IS AN EQUAL OPPORTUNITY EMPLOYER

(W1983)A

PLANT BREEDING INSTITUTE
PLANT PHYSIOLOGIST

required for a period of two years, supported by EEC funding, for research on the drought resistance of dryland rice. The work will involve the testing of breeding lines of rice which differ in their capacity to accumulate abscisic acid and to measure the consequences for growth, tissue water relations and water use efficiency under conditions of limited water supply. Most of the work will be done at Cambridge but a working visit overseas will also be necessary.

Candidates should have a first or upper second class honours degree in an appropriate biological subject, with at least two years' postgraduate experience and a good knowledge of plant water relations.

Appointment will be at Higher Scientific Officer (£7,788 to £10,541 pa). Applications with c.v. and names and addresses of three referees should be sent to the Establishment Officer, Plant Breeding Institute, Maris Lane, Trumpington, Cambridge CB2 2LQ, quoting **reference PHY/219** by 18th July 1985.

Further particulars available on request.

The Institute is an Equal Opportunities Employer. (6919)A

DIRECTOR

Herzberg Institute of Astrophysics
Ottawa, Ontario

The Institute

The National Research Council of Canada invites applications for the position of Director of its Herzberg Institute of Astrophysics whose headquarters are located in Ottawa, Canada. The Institute, which was created in 1975, is engaged in basic research in astrophysics and related topics. It carries out programs in optical and radio astronomy, optical and microwave spectroscopy, and space science.

In addition to its Ottawa laboratories, the Institute operates:
the Dominion Astrophysical Observatory in Victoria, British Columbia
the Dominion Radio Astrophysical Observatory at Penticton, British Columbia
and the **Algonquin Radio Observatory at Lake Traverse, Ontario** and it is a major participant in the support and use of **the Canada-France-Hawaii telescope.**

The Position

Reporting to the Vice-President (Physical Sciences and Engineering), the Director will be responsible for planning, organizing, implementing and controlling the Institute's programs and will advise management on long term research goals. The Institute has a personnel complement of approximately 200, of whom about 50% are professional scientists and engineers, and an annual operating budget of approximately four million dollars excluding salaries.

The Candidate

The person appointed will have an established reputation for outstanding leadership in research and the ability to lead, manage and coordinate the activities of the Institute. Candidates will have a doctorate in astronomy or related physical science and a distinguished record of achievement in science, as well as demonstrated ability in research management.

SALARY will be commensurate with qualifications and is supplemented by a competitive benefits package including relocation allowance.

PLEASE SENT DETAILED RÉSUMÉ IN CONFIDENCE TO:
General Manager

INTERNATIONAL RICE RESEARCH INSTITUTE
POSITION ANNOUNCEMENT — ENTOMOLOGIST

The International Rice Research Institute announces a vacant position for Entomologist at its headquarters in Los Banos, Philippines. The candidate will provide leadership for research and training in host plant resistance. Duties include development of research methodologies using modern instrumentation; insect rearing techniques; research on various aspects of screening rice germplasm for resistance to insects; study of the nature and causes of resistance and emergence of insect biotypes.

The scientist should work closely with plant breeders on the development of insect resistant rice cultivars and in the study of the genetics of resistance to insects in plants; and should direct research programs of PhD, MS, and nondegree scholars.

Candidates should be preferably under 40 years of age, possess a PhD in agricultural entomology with training and experience in host plant resistance. The candidate must be a teamworker and be able to work closely with plant breeders and an inter-disciplinary group of scientists in an international setting. The candidate must have an appreciation of the role of host plant resistance in Integrated Pest Management and have a genuine interest in working with weed scientists, plant pathologists and other entomologists in the development of integrated pest control programs.

IRRI is dedicated to assist developing countries improve the productivity and stability of their rice farming systems. It has well equipped and well staffed laboratories and field research facilities.

Interested persons should apply by 25th July 1985 with a copy of their biodata, a summary of their research accomplishments, a list of their publications and names of three referees to:

Dr. M.S. Swaminathan
Director General
International Rice Research Institute
P.O. Box 933
Manilla, Philippines

(W1975)A

Applications are invited for a position in neurophysiology at the Assistant Professor level in the Department of Physiology at the University of Manitoba Faculty of Medicine. Candidates should have a PhD or equivalent, with two or more years of post-doctoral training. Preference will be given to individuals with experience and a continuing interest in electrophysiological analysis of neural networks and/or neurotransmitter actions using *in vitro* or *in vivo* systems Send curriculum vitae, an outline of future research plans, and arrange for three letters of reference to be forwarded to: **Dr. Henry G. Friesen, Professor and Head, Department of Physiology, The University of Manitoba, 770 Bannatyne Avenue, Winnipeg, Manitoba, R3E 0WE Canada.** Deadline for receipt of applications is 1 September 1985 In accordance with Canadian immigration requirements this advertisement is directed to Canadian citizens and permanent residents.

THE DEPARTMENT OF GENERAL MICROBIOLOGY
of the
UNIVERSITY OF BERN
SEEKS A
PROFESSOR OF MICROBIOLOGY

with particular interests in molecular biology Applicants should be experienced in the area of genetics of eukaryotic microorganisms.

For further information contact Prof R. Braun, Department of General Microbiology, Baltzer-Strasse 4, 3012 Bern.

Applications including CV, list of publications, information of teaching experience, research activity and possible references should be sent by September 15, 1985, to Erziehungsdirektion des Kantons Bern, Abteilung Hochschulwesen, Sulgeneckstr. 70, 3005 Bern, Switzerland. (W1966)A

INTERNATIONAL CROPS RESEARCH INSTITUTE FOR THE SEMI-ARID TROPICS (ICRISAT) near Hyderabad, India

invites applications for

PRINCIPAL GROUNDNUT BREEDER

To assume the leadership of an ongoing international research program in groundnut breeding that aims to produce high-yielding cultivars with resistance on fungal and virus diseases, insects and other pests, and drought, and breeding for earliness, high yield, and quality factors To work in close collaboration with a multidisciplinary team to ensure adequate evaluation of breeding stocks for resistance traits and field performance To develop and evaluate international trials and cooperative projects with national and regional programs. A Ph.D. in Plant Breeding with at least 7 years research experience, an excellent command of written and spoken English, and a willingness and ability to travel frequently are essential. Experience in tropical agricultural and multidisciplinary team research and an ability to speak French are desirable. The appointee will be based at the ICRISAT Center, Patancheru, 30 km NW of Hyderabad Hyderabad offers good access by air to international airports and has good living conditions, and recreational and medical facilities. Educational facilities exist for children to the age of eleven or twelve.

Salary at principal staff level, according to qualifications and experience. Send résumé, including present salary level, and names of three referees, to.

Director General, ICRISAT Patancheru
P.O., A.P. 502 324, India

within 60 days from the date of advertisement.

SIU

UNIVERSITY OF KEELE

'NEW BLOOD' LECTURER IN BIOCHEMISTRY (CELL BIOLOGY)

(re-advertisement)

Applications are invited for a 'New Blood' Lectureship in Biochemistry, tenable from October 1st 1985. Candidates should have experience in mammalian cell biology, preferably in areas related to those of Professor Lloyd's research group, which include pinocytosis, lysosome function and membrane transport. Salary in the range £7,520 — £14,925 pa. Applicants should be 35 or under at the commencement of appointment, and should not currently hold a permanent University appointment in the United Kingdom.

Further particulars and application forms are available from The Registrar, University of Keele, Staffordshire, ST5 5BG. Closing date for applications: 12 July, 1985.

Previous applications will be reconsidered, and re-application is unnecessary. (6918)A

UNIVERSITY OF ABERDEEN
Department of Bio-Medical Physics and Bio-Engineering

LECTURESHIPS (2) IN ELECTRONIC ENGINEERING

Applications are invited for two posts of LECTURER IN ELECTRONIC ENGINEERING applied to Medicine, each with active hospital involvement, to join team of international renown in the Department to design, build and teach modern microelectronic systems. One of the posts is responsible for technical staff on a preventive maintenance service for hospital electronic equipment. Practical people are required who like to roll up their sleeves and make it work.

Salary on Lecturer Scale: £7,520 — £14,925 per annum, with appropriate placing, according to qualification and experience (scale under review).

Further particulars and application forms from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by 22 July 1985. (6921)A

ORGANIC GEOCHEMIST

STANFORD UNIVERSITY

The School of Earth Sciences is intent on adding a new program in organic geochemistry and is seeking an individual with a solid geologic perspective to lead this effort Current research in all four departments in the School including Applied Earth Sciences, Geology, Geophysics, and Petroleum Engineering involves work on sedimentary systems and we view organic geochemistry as an emerging tool of fundamental importance to these studies We also think that organic geochemistry constitutes a field of especially exciting potential for the future studies of the origin and fate of organic matter in modern and ancient sedimentary environments, chemical fossils, sedimentary hosted mineral deposits, petroleum geochemistry, as well as applications to study of the tectonic and sedimentary evolution of continental margins

Applicants for this tenure-track position should have an established research record involving application of organic geochemistry to geological questions, an enthusiasm for teaching, and a clear ability to garner and maintain support for their research program We invite applications from both junior and senior scientists but we are most interested in finding a mid-career scientist of international reputation who is stimulated by the challenge of establishing a new program within the unusually diverse intellectual and geological environment offered by the San Francisco Bay region, Stanford University, and the School of Earth Sciences

Applicants should send a letter outlining their research and teaching interests along with vita including the names of three individuals familiar with their work to

Prof. James C. Ingle, Chairman, Search Committee,
Department of Geology, School of Earth Sciences,
Stanford University, Stanford CA 94305

The level of this appointment is open and may be at Assistant, Associate, or Full Professor depending upon the individual selected Application deadline is September 30, 1985

Stanford University is an Equal Opportunity Employer and we especially encourage applications from women and minority students (NW1882)A

Southampton THE UNIVERSITY

PROFESSOR OF HUMAN MORPHOLOGY

Applications are invited from graduates in medicine or science for an established Chair of Human Morphology. Further details may be obtained from the Secretary and Registrar, the University, Southampton, SO9 5NH, to whom applications (10 copies from persons in the UK) should be sent before 23 August 1985. (6930)A

TWO POSTDOCTORAL POSITIONS

are available immediately for a Ph.D. biochemist and a molecular biologist to participate in studies of gene regulation by steroid receptors. Projects include the purification and characterization of human estrogen and progesterone receptors, cloning of the corresponding genes and preparation of monoclonal antibodies. Experience with steroid receptors, protein purification and analysis, monoclonal antibody production and/or recombinant DNA techniques is desired. Salary is negotiable.

Send curriculum vitae and three letters of references to: Dr Geoffrey L. Greene, The University of Chicago, Ben May Laboratory for Cancer Research, 5841 S. Maryland, Chicago, Illinois 60637. (NW1903)A

Section Leader

Molecular Biology Development

attractive salary + car : Rural South Bucks

Amersham International, a highly successful British company is a market leader producing a wide range of high technology products for life science research, medicine and industry.

We now have an interesting opportunity for an innovative scientist to join our Molecular Biology Development section and lead a team of about ten dedicated professionals in the development of a wide range of novel products to facilitate advances in this field.

To meet the demands of Biotechnology, the section has developed a number of products for DNA sequencing, nick translation, in vitro RNA synthesis, in vitro packaging, in vitro protein synthesis, vectors and hybridisation membranes, as well as its renowned high quality radiochemicals. The section plays an increasingly important role in the Division's business strategy and is currently developing an important range of new products.

Reporting to the head of Molecular Biology Development, you will be responsible for helping to identify new product opportunities and for developing these through your team to the successful launch of new products.

Probably a post-doctoral scientist with several years' experience in recombinant DNA technology you must be able to demonstrate a blend of managerial skills and appropriate technical knowledge vital for this position.

Salary will reflect both qualifications and experience and will be enhanced by a benefits package which includes 25 days' holiday, a generous pension scheme, and relocation assistance, where appropriate.

Please write, detailing your career to date, to Simon Voake (SV) at the address below or telephone Little Chalfont (02404) 4488, ext. 3569 for an application form.

FACULTY POSITIONS IN ELECTRICAL ENGINEERING (SOLID STATE DEVICE AND MICROELECTRONICS AREA)

The Pennsylvania State University at University Park, Pennsylvania invites applications for tenure track faculty positions at the Assistant Associate and Full Professor ranks in Electrical Engineering in the area of Solid State Device and Microelectronics Applicants should have an earned doctorate in electrical engineering, engineering physics or related fields, and have demonstrated the ability to conduct research and teaching in the field of Solid State Device and Microelectronics

The successful candidates are expected to join the existing effort in the solid state device research and help develop it into one of prominence. The College of Engineering has made substantial commitments to support this program by hiring of an endowed professor in this area

Currently, research in the solid state device and related materials area includes research in silicon device processing, such as plasma and reactive ion etching, thermal nitridation of silicon and various oxide research including ultra-thin oxides, and defect control. In addition, research in III-V device area includes material defects, electrical noise and performance improvement of micron and sub-micron stuctures

Combined research in the solid state device area typically amounts to about one million dollars annually Collaborative research opportunities exist with the Materials Science department, Engineering Science and Mechanics department, the Chemistry and the Physics departments and the Materials Research Laboratory at Penn State.

Résumés, or inquiries should be directed to the following address by no later than September 15, 1985, or until suitable candidates are identified

Department of Electrical Engineering
Box H, 129 Electrical Engineering East
University Park, PA 16802

An Equal Opportunity/Affirmative Action Employer (NW1909)A

UNIVERSITY OF DUNDEE

Ninewells Hospital and Medical School

DEPARTMENT OF OBSTETRICS AND GYNAECOLOGY

POST-DOCTORAL SCIENTIST (IN VITRO FERTILIZATION)

A Post-Doctoral Scientist, with a PhD in some area of biological or medical science, is required to undertake research and supervise a laboratory for in vitro fertilisation in the treatment of human fertility within the Division of Obstetrics and Gynaecology in a newly funded Unit of Reproductive Medicine. Equal emphasis is placed on the research potential of IVF, cryopreservation, and other areas relevant to infertility

A cytogeneticist as well as supporting technical and clerical/secretarial staff are also to be appointed and the on-site facilities, which are excellent, include an endocrine laboratory.

The appointment is available at this stage for three years and will be made within the Research and Analogous Staff Range IA scale (currently £7,520 — £12,150 but due for revision) with initial placing dependent of qualifications and experience

Enquiries about the post may be made to Dr John Mills at Ninewells Hospital and Medical School (telephone Dundee (0382) 60111)

Applications (2 copies) containing full career details and the names of 3 referees should be sent by 11th July 1985 to the Personnel Officer, The University, Dundee DD1 4HN. Please quote reference EST/72/85J (6922)A

PUBLIC HEALTH LABORATORY SERVICE BOARD

PHLS Centre for Applied Microbiology and Research

VACCINE RESEARCH AND PRODUCTION LABORATORY

Basic Grade Microbiologist

A research programme has been initiated to develop a live attenuated vaccine against Rift Valley Fever. The programme is a collaborative project between VRPL in CAMR and the NERC Institute of Virology at Oxford The work at CAMR will fall into two categories Firstly the location of the genetic material coding for the attenuated virus phenotype will be determined. Secondly, in vivo model systems for Rift Valley Fever will be used to compare the pathology of virulent and attenuated virus strains.

Applicants should have a good degree in Microbiology and/or Biochemistry. Preference will be given to candidates with previous research experience in animal virology

The post will be for 3 years and further details can be obtained from Dr J R Stephenson (Tel. (0980) 610391)

Salary: £6,559 rising to £7,063 by annual increments

National Health Service terms and conditions will apply.

Closing Date: 31 July 1985

Application forms are obtainable from the Personnel Officer, PHLS Centre for Applied Microbiology & Research, Porton Down, Salisbury, Wiltshire SP4 0JG. Telephone Idmiston 610391.

Please quote Post No 72 when applying (6924)A

UNIVERSITY COLLEGE CORK

RESEARCH POSITIONS IN MICROBIOLOGY/ BIOTECHNOLOGY

POSTDOCTORAL RESEARCH ASSOCIATES (2)

To work on projects involving molecular genetics of plant-microbial interactions —

(a) To investigate genes involved in carbon metabolism in rhizobium (Genetic Engineering)

(b) To investigate the regulation of carbon metabolism in Rhizobium and plant growth promoting pseudomonas SPP. (Biochemical-Genetics/ Physiology)

Positions are available from 1 July 1985 and salary will be in the range - IR£8,596 — IR£11,173 (less PRSI contribution) according to experience.

Applications including a cv and the names of two referees should be sent as soon as possible to Dr F O'Gara, Microbiology Department University College, Cork, Ireland, from whom further particulars are available. (6885)A

UNIVERSITY OF DURHAM

LECTURESHIP IN THEORETICAL PHYSICS

Applications are invited for a 'New Blood' Lectureship in Theoretical Particle Physics to be held jointly in the Departments of Mathematical Sciences and Physics and tenable from 1 October 1985 or as soon as possible thereafter. The successful applicant may work on any aspect of theoretical particle physics.

Salary on the scale £7,520 — £14,925 with USS (under review)

Applications (3 copies) naming three referees should be sent by 19 July 1985 to the Registrar, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. (6927)A

RESEARCH ASSOCIATE

Position available as of 1 October 1985 for the duration of up to 5 years (the salary will be in the range of DM 65.000, — to 70 000, — according to BAT II/III tariff) The project involves investigation of primary processes of water cleavage in photosynthesis Method: pulse spectroscopy, biochemistry, ESR, etc.

Applicant should have a very good degree in chemistry or physics Knowledge of German is desired Possibility for further qualification (ie PhD) is given

Applications with two references should be addressed to: Prof Dr H T Witt, Max-Volmer-Institut for Biophysical and Physical Chemistry, Technische Universitat Berlin, Strasse des 17 Juni 135, 1000 Berlin 12 (W1972)A

THE UNIVERSITY OF SUSSEX

LECTURER IN PLANT PHYSIOLOGY

in the School of Biological Sciences, from 1st October 1985 to 30th September 1986. Applications are invited from qualified men and women with a primary interest in Environmental Physiology

Salary on the Lecturer scale £7,520 to £14,925 pa.

Send self-addressed envelope (6" × 9") for further particulars and an application form to Mrs L Vivian, Personnel Office, The University of Sussex, Falmer, Brighton, BN1 9RH. Closing date for applications Friday 19th July 1985 (6979)A

UNIVERSITY OF LONDON

British Postgraduate Medical School

THE CARDIOTORACIC INSTITUTE at the BROMPTON HOSPITAL

CYSTIC FIBROSIS DEPARTMENT

MLSO

Required for routine and research work involving contact with patients. Experience in immunological techniques desirable Salary depending on age and experience, range £5,738 — £6,726 + £1,084 London Weighting. The post is for one year initially.

Applications, together with curriculum vitae and names and addresses of two referees to The Secretary, Cardiothoracic Institute, Fulham Road, London SW3 6HP by 8 August 1985 (6977)A

THE ROWETT RESEARCH INSTITUTE
Bucksburn, Aberdeen, AB2 9SB

MICROBIAL GENETICIST/ BIOCHEMIST HSO/SSO GRADE

Applications are invited for this post in the Microbial Biochemistry Department

The Rowett Research Institute is the foremost agricultural institute in the UK carrying out fundamental research into the nutrition of man and farm animals. The Microbial Biochemistry Department contributes to this programme in studying the microbiology of the alimentary tract as it relates to the nutrition of the host animal A highly innovative young scientist is required to initiate studies which will examine the rumen from a new angle, that of a genetic ecosystem Areas likely to be explored in the first instance are the spread of resistance factors to feedlot antibiotics in vivo and in mixed cultures in vitro, and the regulation of expression of enzymes involved in the breakdown of plant fibre and protein

The successful applicant will probably be a PhD graduate with some postdoctoral experience. A genetics background might be helpful but is not essential More importance is attached to the scientific ability of the candidate Scientists with a more general microbiology, biochemistry and molecular biology experience are therefore encouraged to apply. Training in rumen microbiology will be given within the Institute, and it is envisaged that a proportion of the work in the first year will be done at a leading microbial genetics laboratory in the UK.

Qualifications— First or upper second class honours degree in Microbiology, Biochemistry or related subject with at least 2 years relevant post-graduate experience for HSO grading and 4 years for SSO

Salary Scales.— HSO £7,788 to £10,541 pa, SSO £9,772 to £12,653 pa, with placing according to experience.

The position is Superannuable and the Institute is an Equal Opportunities Employer.

Applications in writing together with full CV and the names/ addresses of 2 referees should be sent to the Secretary of the Institute from whom further particulars are available. Tel. 0224 - 712751 (Ext 338).

Closing date 18th July 1985. (6917)A

UNIVERSITY OF LONDON
INSTITUTE OF PSYCHIATRY
DEPARTMENT OF PSYCHOLOGY
Brain, Behaviour and Psychiatry Research Group

POSTDOCTORAL RESEARCH WORKER AND RESEARCH STUDENT

to work on the application of electrochemical methods (in vivo intracerebral voltammetry) to the study of behaviour in the rat Applicants should have training in either the biological aspects of psychology or biochemistry, electrochemistry or pharmacology

Salary for the two-year postdoctoral appointment (MRC-supported) will be £7,520 — £9,860 pa plus £1,233 London Allowance on the 1A scale for research workers, the Research Studentship will be on the same terms as an MRC Studentship.

Application forms for the Research Worker are available from the Assistant Secretary, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF quoting Ref JG/N.

Applications for the Research Student, with the names of two referees, should be sent to Professor J A Gray, Department of Psychology, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF

Closing date for applications 12 July 1985. (6940)A

CHARING CROSS AND WESTMINSTER MEDICAL SCHOOL
(University of London)
DEPARTMENT OF BIOCHEMISTRY

POST-DOCTORAL RESEARCH FELLOW and RESEARCH TECHNICIAN

Applications are invited for the above posts for a 3-year project on the action of heparin and heparin sulphate and their derivatives on vascular smooth muscle cell matrix synthesis. Starting salary up to £8,920 pa plus £1,233 pa London Allowance for the Post-doctoral post and up to £6,420 pa plus £1,084 pa London Allowance for the Technician depending on age and experience

Applicants should have a degree, or equivalent, in biochemistry, cell biology or related discipline Previous experience in tissue culture and/or extracellular matrix biochemistry would be an advantage. Further details from Dr R M Mason, Tel: 01-741 1958.

Applications including a full curriculum vitae and the names of two academic referees should be sent to The Secretary, Charing Cross and Westminster Medical School, The Reynolds Building, St Dunstan's Road, London, W6 8RP, as soon as possible after the appearance of this advertisement (6936)A

THE UNIVERSITY OF NEW ENGLAND
Department of Biochemistry, Microbiology & Nutrition

RESEARCH INTO MODIFICATION ON RUMEN FERMENTATION

SENIOR POSITION — MOLECULAR BIOLOGIST

Equal Opportunity is University Policy

A Molecular Biologist is required to establish a research group to study manipulation of rumen microbes using recombinant DNA techniques with a view to increasing fermentation of lignified forages.

This new group will join an existing group of nutritional biochemists and microbiologists led by Dr J. Nolan and Professor R. Leng. Dr T. Bauchop recently accepted appointment as Senior Microbiologist with the group.

The appointment is available immediately. It will be for three years initially, when the whole programme will be reviewed by the Australian Meat Research Committee which is funding the project.

The appointee will be expected to attract and supervise postgraduate students as part of his/her duties

Applicants must have extensive experience, research ability and a publication record appropriate to senior levels of appointment.

Informal enquiries to Professor Leng 067 73-2707.

Appointment will be dependent on experience, qualifications, and ability in one of the ranges:

Professorial Fellow	**A$54,948 pa**
University Fellow	**A$46,397 pa**
Senior Research Fellow	**A$35,203 — A$41,029 pa**

Assistance with travel and removal expenses available.

CLOSING DATE: 1st August 1985
POSITION NO: 502

Applications including the names and addresses of three referees and stating the position number should be sent to the Staff Officer, University of New England, Armidale N.S.W. 2351, prior to the closing date. Applicants should forward a copy of this advertisement to their referees and ask them to send their reports direct to the Staff Officer, Mr B.G. Turner, marking their envelopes 'Private and Confidential' and quoting the position number, before the above closing date so as to expedite the appointment process. (W1981)A

THE NATURE CONSERVANCY COUNCIL

HIGHER SCIENTIFIC OFFICER (Freshwater Botanist)

The Scottish field unit and the Chief Scientist's Directorate intend to appoint a botanist to carry out a survey of freshwater loch on Speyside and in the N of Scotland The contract, which will be for approximately two years in the first place, but is likely to be rewarded for at least a further year, will be based at Edinburgh

Qualifications and Experience: Applicants should have a good degree in botany or another appropriate biological subject, and at least two years postgraduate experience of freshwater survey work They must have a good working knowledge of water-plants and be able to drive.

Salary — Depending on qualifications and relevant experience, £7,435 rising to £10,039.

For further details and an application form please contact Mr S Woodfield, Personnel 1, Nature Conservancy Council, Northminster House, Peterborough, PE1 1UA to whom completed application forms should be returned by the 18 July 1985.

The Nature Conservancy Council is an equal opportunity employer. (6935)A

Dunn Nutrition Unit Cambridge

SCIENTIST

Applications are invited from Post Doctoral Scientists with experience in human energy metabolism, to join a team studying nutrition and health in our field station in rural Gambia. The proposed studies involve the use of a whole-body indirect calorimeter to investigate physiological adaptations to low energy intakes with particular emphasis on pregnancy and lactation The successful candidate will be expected to take joint charge of these studies and to co-ordinate them with our programme of stable isotope research.

The appointment will initially be for two years of which 2-3 months will be spent in Cambridge and Lausanne, Switzerland, undergoing training in calorimetery techniques The remaining time will be spent in our Gambia field station with six weeks home leave after one year. Depending on progress there should be a possibility of extension for a further two years The appointment will start in October 1985. Salary in the range of £8,920 — £11,205 plus overseas allowances

Please send applications with a full cv and the names of three referees to Dr R G Whitehead, MRC, Dunn Nutrition Unit, Milton Road, Cambridge CB4 1XJ

Closing date 15 July 1985 (6971)A

LEONHARD PROFESSORSHIP IN SOLID STATE DEVICE ENGINEERING

Applications and nominations are invited for a recently endowed professorship in Solid State Device Engineering within the Department of Electrical Engineering at The Pennsylvania State University. Applicants should have an earned doctorate in electrical engineering, engineering physics, or a related field, and have demonstrated the ability to conduct research and teaching in the field of Solid State Device and Microelectronics Strong leadership qualities are also emphasized

The successful applicant is expected to join the existing effort in solid state device research and help expand and develop it into one of prominence in both research and instruction. The College of Engineering has made substantial commitment to support this program including updating of the laboratory facilities and new faculty hiring.

Currently, research in the solid state device and related materials area includes research in silicon device processing, such as plasma and reactive ion etching, thermal nitridation of silicon and various oxide research including ultra-thin oxides, and defect control. In addition, research in III-V device area includes material defects, electrical noise and performance improvement of micron and sub-micron structures.

Combined research in the solid state device area typically amounts to about one million dollars annually. Collaborative research opportunities exist with the Materials Science department, Engineering Science and Mechanics department, the Chemistry and the Physics departments and the Materials Research Laboratory at Penn State.

Résumés, nominations, or inquiries should be directed to the following address by no later than September 15, 1985, or until a suitable candidate is selected.

Chairperson, Leonhard Professor Search Committee
Department of Electrical Engineering
Box J, 129 Electrical Engineering East
The Pennsylvania State University
University Park, PA 16802

An Equal Opportunity/Affirmative Action Employer. (NW1910)A

IGNEOUS PETROLOGY

Université de Montréal, Faculté des arts et des sciences, Département de géologie

A TENURE-TRACK POSITION IN INGEOUS PETROLOGY

Fonction Duties: To carry out active research in his/her field of interest and to teach and advise students at the graduate levels.

Qualifications: Ph.D. or equivalent is required.

Salary: In accordance with the collective agreement.

Application deadline: September 3, 1985.

In accordance with Canadian immigration requirements, priority will be given to Canadian citizens and permanent residents of Canada

Applications, together with curriculum vitae and names of three referees, should be sent to: M. Bernard Mamet, directeur, Département de géologie, Faculté des arts et des sciences, Université de Montréal, C.P. 6128, succursale A. Montréal (Québec) H3C 3J7, CANADA. (NW1905)A

MEDICAL RESEARCH COUNCIL

National Institute for Medical Research

DIVISION OF PARASITOLOGY

Applications are invited for a postdoctoral position to work with Dr C.J. Sanderson for a period of three years. The project is to work on a recently identified lymphokine controlling eosinophil differentiation. An interest in cell differentiation or molecular biology would be an advantage.

The salary will be in the range £8,920 — £10,720 per annum plus £1,233 London allowance, with superannuation provision.

Applications, together with curriculum vitae, research experience and interests and the names of two professional referees should be sent to the Director, National Institute for Medical Research, The Ridgeway, Mill Hill, London NW7 1AA before 26th July 1985, quoting Ref: P/9/WH0/S. (6949)A

UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH ASSOCIATE

Applications are invited for an SERC funded post to work on the mechanisms by which globular proteins fold into their active state. Spectroscopic scattering, hydrodynamic and monoclonal antibody techniques will be used to study naturally occurring, mutant and recombinant proteins. The appointment is for three years tenable from September 1985 or soon after

Salary will be up to £7,980 per annum on the Range 1A salary scale: £7,520—£12,150 per annum according to age, qualifications and experience

Candidates with PhD or expecting to have gained a PhD by the autumn should send applications with curriculum vitae and the names and addresses of three referees to Professor R H Pain, Department of Biochemistry, University of Newcastle upon Tyne, NE1 7RU by July 18th. (Telephone 0632 328511 Ext 3437) (6929)A

THE UNIVERSITY OF MANCHESTER

POST-DOCTORAL RESEARCH POST

Applications are invited for this post, tenable in the Department of Medicine at Hope Hospital, Salford (Head of Department Professor L A Turnberg). The successful applicant will work on the electrophysiology of the colon in health and disease. Experience of intracellular microelectrode techniques would be an advantage. The post is for 2 years commencing from a date to be arranged Initial salary pa. £7,520 — £8,920 depending on experience Superannuation.

Further details may be obtained from Dr G I Sandle, Department of Medicine, Clinical Sciences Building, Hope Hospital, Salford M6 8HD (tel 061-789-7373 ext 236), to whom applications should be returned by July 22nd. (6960)A

LEUKAEMIA RESEARCH FUND CENTER AT THE INSTITUTE OF CANCER RESEARCH

A TECHNICIAN

is required for a post in the above laboratory based at Fulham Road, London SW7. The work will involve cell culture and cloning of human and mouse haemopoietic cell lines required for studies on genetic alterations in leukaemia. Experience in tissue culture is essential.

Salary in the range of £5,738 — £6,924 pa plus £1,042 London Weighting Allowance dependent on age and experience.

Applicants are advised that in the majority of the Institute's premises smoking is prohibited. Applications in duplicate with the names of two referees to the Personnel Officer, Institute of Cancer Research, 17A Onslow Gardens, London SW7 3AL quoting reference 301/B/89/N. (6969)A

THE UNIVERSITY COLLEGE WALES ABERYSTHWYTH

DEPARTMENT OF AGRICULTURE

Applications are invited for the post

RESEARCH ASSISTANT

to work on the effects of environment and cultural practices on the crisping quality in early harvested potato crops The project is supported by a grant from the Potato Marketing Board and be tanable for three years

Candidates should possess a good Honours degree in Agriculture or a relevant Agricultural or Biological Science, the person appointed may register for a higher degree Salary on the IB Range for Research and Analogous Staff £6,600—£8,920 per annum.

Applications forms and further particulars can be obtained from the Registrar (Staffing Officer), The University College Wales, Old College Kings Street, Aberysthwyth, Dyfed SY23 2AX (Tel No: 0970 — 3177 Ext. 207). Closing date for applications Friday 19 July 1985 (6984)A

YALE UNIVERSITY The Department of Chemistry invites applications for two tenure track Assistant Professor positions, effective academic year 1986

We seek outstanding individuals in any field of chemistry Applications from those whose research interests overlap with the areas of organic or inorganic chemistry and the biological sciences are particularly welcome

Applicants should send a curriculum vitae, a statement of research plans, and should arrange for the submission of three letters of recommendation All materials should be received by December 1, 1985

Send application to Prof. S.L. Schreiber, Chairman, Search Committee, Department of Chemistry, Yale University, P.O. Box 6666, New Haven, CT 06511. Yale University is an EO/AA employer. (NW1895)A

UNIVERSITY OF LEICESTER

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a postdoctoral position to work with Dr Colin W Jones (in collaboration with Dr John R Linton, Shell Research) on the physiology and energetics of metabolite production in bacteria

Applicants should have experience in microbial physiology or biochemistry.

The position is for three years and the initial salary will be in the range £7,520 — £12,150 per annum, plus superannuation

Applications, including a curriculum vitae and the names and addresses of three referees, should be sent by July 19th to Mrs J Dean, Department of Biochemistry Secretary, University of Leicester, Leicester LE1 7RH (6923)A

ROTHAMSTED EXPERIMENTAL STATION

Harpenden, Herts AL5 2JQ

ORGANIC CHEMIST

with good practical ability required by the Insecticides and Fungicides Department to work in a team synthesizing powerful insecticides related to the pyrethrins. Excellent instrumental facilities available. This temporary two year post is funded by the British Technology Group to exploit promising previous work The appointment should start as soon as possible.

Qualifications: First or Upper Second Class honours degree and at least two years post-graduate experience A PhD in a relevant field of organic chemistry would be an advantage.

Appointment in the grade of Higher Scientific Officer on scale £7,788—£10,541. Non-contributory superannuation

Apply in writing to the Secretary, naming two referees and quoting Ref. 595 by 17 July 1985. Further particulars on request. (6947)A

THE UNIVERSITY OF LEEDS
DEPARTMENT OF PLANT SCIENCES
POSTDOCTORAL RESEARCH FELLOW

Applications are invited for the above post for work on a project supported by ICI to study the growth and development of winter barley. The appointment will be made for a fixed period of up to three years, beginning in September

Applications should have, or shortly expect to receive, a PhD in agricultural science or crop physiology. Experience in field studies of growth and development in cereals is desirable.

Initial salary up to £9,860 a year (under review) on the 1A Range for Research and Analogous Staff (£7,520 — £12,150) (under review) according to age, qualifications and experience

Informal enquiries may be made to Professor J Elston (Tel: 0532 431751 ext 377).

Application forms and further particulars may be obtained from the Registrar, The University of Leeds, Leeds LS2 9JT, quoting reference no 53/27 Closing date for applications 18 July 1985. (6963)A

OXFORD POLYTECHNIC
DEPARTMENT OF GEOLOGY AND PHYSICAL SCIENCES
LECTURER II/ SENIOR LECTURER IN GEOPHYSICS
POST NO.

The Department of Geology and Physical Sciences invites applications for the permanent post of Lecturer II/Senior Lecturer in Geophysics, the successful applicant to take up the post on 1 September 1985, or as soon thereafter as possible.
The appointee will be expected to teach Geophysics are related aspects of Geology to Honours Degree level Earth Scientists and to give a course in Geophysics as part of the Oxford Polytechnic Postgraduate Diploma in Petroleum Exploration Geology. In addition, there is a strong possibility that an opportunity will exist for collaboration with the National School of Mines in Rabat, Morocco. Any such collaboration may lead to salary enhancement. The successful applicant will be joining a strong team of Geologists at Oxford Polytechnic and will be expected to undertake research and/or consultancy.
Applications are invited from suitable qualified candidates holding an Honours Degree in Geology or related science and with postgraduate experience in Geophysics. A background which includes Geophysical research and/or industrial experience will be an advantage and preference may be given to those with experience in seismic interpretation
Basic Salaries.
Senior Lecturer:
£11,175 — £14,061 (under review)
Lecturer II
£7,548 — £12,099 (under review)
Closing date for completed application forms
For further details and application forms, pleasy apply to the Staffing Office, Oxford Polytechnic, Gipsy Lane, Headington, Oxford OX3 0BP. Telephone Oxford 64777, Extension 364. Closing date July 15th 1985.
An Equal Opportunities Employer
(6966)A

MEDICAL RESEARCH COUNCIL
Dunn Nutrition Unit, Cambridge
SCIENTIST

Applications are invited from Post Doctoral Scientists with experience in human energy metabolism, to join a team studying nutrition and health in our field station in rural Gambia. The proposed studies involve the use of a whole-body indirect colorimeter to investigate physiological adaptations to low energy intakes with particular emphasis on pregnancy and lactation. The successful candidate will be expected to take joint charge of these studies and to co-ordinate them with our programme of stable isotope research

The appointment will initially be for 2 years of which 2 to 3 months will be spent in Cambridge and Lausanne, Switzerland undergoing training in calorimetry techniques The remaining time will be spent in our Gambia field station with 6 weeks home leave after one year. Depending on progress there should be a possibility of extension for a further two years. The appointment will start in October 1985

Salary in the range £8,920 — £11,205 plus overseas allowances

Please send applications with a full cv and the names of three professional referees to Dr R G Whitehead, MRC Dunn Nutrition Unit, Milton Road, Cambridge CB4 1XJ.

Closing date for applications is 15 July 1985. (6982)A

ROYAL POSTGRADUATE MEDICAL SCHOOL
DEPARTMENT OF MEDICINE
MRC Clinical Immunology Research Group
CHIEF TECHNICIAN

Applications are invited for the post of Chief Technician in this Unit which is vacant at present. The group is headed by Professor D K Peters with its main interests in the clinical immunology of autoimmunity, nephritis and persistent virus infections, it comprises approximately 12 scientists and research fellows and 10 Technicians. The successful applicant would be responsible for the administrative running (including ordering and supervision of equipment) of the laboratories, and training of technicians However they would also be expected to have a keen interest and to participate in experimental work and should have a background in immunological research

Interested applicants are invited to visit the Unit by contacting Dr J G P Sissons (01-743 2030 ext 345)

Salary on scale £9,458 to £10,975 plus £1,084 London Allowance a year.

This is a readvertisement, previous applicants need not apply.

Application forms and further particulars from the Personnel Office Royal Postgraduate Medical School, 150 Ducane Rd, London W12 0HS quoting ref: 2/110/N

Closing Date: 18 July 1985.
(6973)A

LH FERMENTATION

Due to continued expansion, LH Fermentation who are leaders in the manufacture and distribution of Fermentation and Biological Culture equipment on a world-wide basis, have a requirement for Sales Personnel in both their Home and Export Sales Departments. The successful applicant will have experience of medium to large scale microbial or mammalian cell culture.

EXPORT SALES EXECUTIVE

Based in our Stoke Poges office the Export Sales Executive will be responsible for the technical support of our Scandinavian and Western European markets The successful candidate will be prepared to travel extensively within these markets and have the personal drive and ambition to succeed in this important environment
Although previous Export Sales experience would be an advantage, full Sales and Documentation training will be given to the successful applicant
A company car will be provided Salary dependent on experience
Please send full C V in confidence to
Mr. S M Asbridge, Export Sales Manager, LH Fermentation Ltd, Bells Hill, Stoke Poges, Bucks SL2 4EG Tel.02814 5100.

UK TECHNICAL SALES REPRESENTATIVE

Reporting to our Stoke Poges office, the successful candidate will cover the London and South East area Previous sales experience is not required as full professional sales training will be given
A company car will be provided Salary dependent on experience
Please send full C V in confidence to
Mr. R. Foster, UK Sales Manager, LH Fermentation Ltd, Bells Hill, Stoke Poges, Bucks SL2 4EG. Tel.02814 5100.

LH
THE WORLD STANDARD IN BIOTECHNOLOGY
LH Fermentation Ltd is a Porton International Group Company

HOUGHTON POULTRY RESEARCH STATION
Grant-Aided by the Agricultural & Food Research Council
TEMPORARY MOLECULAR BIOLOGIST

Applications are invited for the above post to work on molecular aspects of pathogenesis of Marek's disease Areas of interest are in situ hybridization and characterization of RNA transcripts and their translated products in infected cells.

Candidates should have recently completed a PhD degree or be graduates with experience in molecular biology of nucleic acids A background in virology would be an advantage but is not essential

The post is for a period of 2 years and is supported by the Leukaemia Research Fund Informal enquiries to Dr N Ross (Tel 0480–64101).

The appointment will be made to the Higher Scientific Officer grade (salary £7,788 × 6 — £10,541) or the Senior Scientific Officer grade (salary £9,772 × 7 — £12,653) depending on experience and qualification.

An application form and further particulars may be obtained from the Secretary, Houghton Poultry Research Station, Houghton, Huntingdon, Cambs The closing date for applications is 25th July 1985. (6972)A

THE ANIMAL VIRUS RESEARCH INSTITUTE
Ash Road, Pirbright, Woking, Surrey GU24 0NF
HIGHER SCIENTIFIC OFFICER

Following the restructuring of the Animal Virus Research Institute, applications are invited for a new post of Higher Scientific Officer to work in the Division of Molecular Biology, Director's Group. The appointment to commence as soon as possible The successful candidate will work on the mechanisms of replication of fowl plague virus RNA.

Candidates should have a First or Upper Second Class Honours degree with at least two years post graduate qualifying relevant research experience.

Salary scale £7,788 — £10,541, sick leave and non-contributory superannuation schemes, 22 days annual holiday. House may be available for suitable married applicant

Applications to include a curriculum vitae and the names of two referees should be sent as soon as possible to. The Secretary, The Animal Virus Research Institute, Ash Road, Pirbright, Woking, Surrey GU24 0NF. Tel: 0483 232441/8.

The Animals Virus Research Institute is an Equal Opportunities Employer (6945)A

UNIVERSITY OF UTAH

As part of a cooperative program with the Department of Biology, the Department of Chemistry is inviting applications for a tenure-track Assistant Professorship for individuals whose research interests are in the area of structure and function of biological macromolecules. The selected candidate is expected to demonstrate excellence and creativity in research and to play an active role in teaching. Preference will be given to individuals who apply modern chemical methods to the study of proteins or nucleic acids in areas which complement existing programs.

Send résumé including a description of research plans and three letters of reference by 10/1/85 to Professor C.D. Poulter, Department of Chemistry, University of Utah, Salt Lake City, Utah 84112. The University of Utah is an equal opportunity/affirmative action employer. (NW1918)A

EXCITING RESEARCH OPPORTUNITY IN WEST GERMANY

CELL BIOLOGIST

With experience in light and electronmicroscopic techniques and their application to immunological and biochemical studies at the cellular and sub-cellular level. The ideal candidate should have an MD and/or Ph D, and postdoctoral experience.

In addition to the researcher's salary, this federally funded position includes salary for a Technician, start-up funds and an appropriate supply budget.

Please send CV and references to:
Dr. Rolf Kinne
Director Max-Planck-Institut fuer Systemphysiologie
Rheinlanddamm 201
4600 Dortmund 1, West Germany. (W1953)A

UNIVERSITY OF OXFORD

PROFESSORSHIP OF THE PHYSICS AND CHEMISTRY OF MINERALS

The electors intend to proceed to an election to the newly established Professorship of the Physics and Chemistry of Minerals. The stipend of the professorship is at present £20,795.

Applications (ten copies, or one from overseas), naming three referees but without testimonials, should be received not later than 27 August by **The Registrar, University Offices, Wellington Square, Oxford OX1 2JD,** from whom further particulars may be obtained. (6970)A

POSTDOCTORAL RESEARCH ASSOCIATE

in the field of Membrane Physical Biochemistry

Multinuclear NMR and fluorescence studies of the physical properties of model membranes, particularly with reference to the mechanism of action of anesthetics and alcohol The successful candidate should have a Ph.D. in chemistry or biochemistry. Possibility of interviews at Amsterdam Biochemistry Congress for finalists.

Send Curriculum Vitae and three letters of reference to: Elizabeth S. Rowe, Ph.D., Veterans Administration Medical Center, Research Service (151), 4801 Linwood Blvd., Kansas City, MO 64128; telephone 816-861-4700 ext 541. (Affiliated with the Biochemistry Department of the University of Kansas Medical Center.) (NW1913)A

UNIVERSITY OF SASKATCHEWAN

Institute of Space and Atmospheric Studies

PROFESSIONAL RESEARCH ASSOCIATE

An opening, available immediately, exists for a Professional Research Associate to work with a small research group in the general area of photochemistry of planetary atmospheres and with particular reference to oxygen chemistry The work will involve the analysis of data obtained from experiments previously flown on the Space Shuttle Candidates should have post-doctoral experience, preferably in the study of planetary atmospheres.

Those interested should write to Dr E.J. Llewellyn, Institute of Space and Atmospheric Studies, University of Saskatchewan, Saskatoon, Saskatchewan S7N OWO The salary will not be less than $26,000 per annum. (NW1907)A

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF ANATOMY AND EMBRYOLOGY

RESEARCH ASSISTANT (IA)

This postdoctoral position is available for one year in the first instance, but with the possibility of extension up to three years on an MRC grant concerned with Localisation of Neurotransmitter Receptors in the Autonomic Nervous System Scientists with experience in autoradiography, electronmicroscopy, immunohistochemistry or pharmacological or biochemical aspects of receptor biology will be particularly suited. The technical and intellectual environment for research is attractive. Salary in range £5,520 — £10,330 + £1,233 LA according to age and experience.

Applications, together with full cv and names and addresses of two referees, to Professor G Burnstock, Department of Anatomy & Embryology, University College London, Gower Street, London WC1E 6BT. (6946)A

LEUKAEMIA RESEARCH FUND CENTRE AT THE INSTITUTE OF CANCER RESEARCH:

TECHNICIAN/RESEARCH OFFICER

required to help organise a molecular biology laboratory and actively participate in its research programme into Cellular and Molecular Biology of Human Leukaemia. Experience in recombination DNA techniques essential Candidates should have a degree, HNC or equivalent qualification.

Salary will be in the range of £5,738 — £8,096 + £1,042 pa. London Weighting allowance, depending on qualifications and experience Applicants are advised that in the majority of the Institute's premises smoking is prohibited.

Applications in duplicate with the names and addresses of two referees should be sent to the Personnel Officer, Institute of Cancer Research, 17A Onslow Gardens, London SW7 3AL, quoting reference 301/B/86 (6862)A

MRC

Medical Research Council

MEDICAL RESEARCH COUNCIL

Toxicology Unit

PROTEIN BIOCHEMIST/ CHEMIST

A 3 year post-doctoral appointment (usual MRC terms) is available to characterise a membrane bound protein involved in the maintenance of nerve cell axons. The initial objective is to improve existing partial purification procedures for the active-site radiolabelled enzyme to the point where sequencing etc, is practicable. Skills in protein biochemistry including affinity chromatography and liquid phase partitioning are required and acquaintance with molecular biology techniques would be an advantage

Applications to Dr. M.K. Johnson, MRC Toxicology Unit, Woodmansterne Road, Carshalton, Surrey SM5 4EF. (6964)A

UNIVERSITY OF DUNDEE

EPARTMENT OF BIOCHEMISTRY

MRC Protein Phosphorylation Group

POSTDOCTORAL WORKER/RESEARCH ASSISTANT

pplications are invited for the bove position to work with Pro-ssor Philip Cohen, FRS on the role f protein phosphorylation in hor-one action. The position, which ecomes vacant in August 1985, is or three years in the first instance he appointment will be made at an ppropriate point on the Research nd Analogous Scale Range 1A urrently £7,520 — £12,150) de-ending on qualifications and ex-erience A background in Protein hemistry and Enzymology, or olecular Pharmacology, would be n advantage Informal enquiries an be made to Professor Cohen, elephone number Dundee 23181, xtension 4238.

Applications containing a full cur-iculum vitae and the names and ddresses of three referees should be ent to the Personnel Office, The Jniversity, Dundee, DD1 4HN as oon as possible. Please quote refer-nce EST/73/85J (6934)A

POSTDOCTORAL POSITION

Available for research on the isolation of herbicide resistant microbial genes and their subsequent expression in plant cells Expertise in recombinant DNA technology and yeast molecular biology is required.

Send C.V. and two letters of reference to: Dr G.H. RANK, DEPT. OF BIOLOGY, UNIVERSITY OF SASKATCHEWAN, SASKATOON, SASK., CANADA S7N OWO. (NW1906)A

POSTDOCTORAL PROTEIN CRYSTALLOGRAPHER

Positions are available for two crystallographers to study the structure of myosin subfragment-1. The research involves protein purification, crystal growth and data collection. Applicants with experience in any aspect of crystallography will be considered Salary commensurate with experience **Send résumé and three letters of recommendation to: Dr. Ivan Rayment, department of biochemistry, University of Arizona, Biological Sciences West, Tucson, Arizona, 85721, USA.** The University of Arizona is an equal opportunity employer (NW1900)A

ASTON UNIVERSITY

Auditory Physiology Laboratory

DEPARTMENT OF PHARMACEUTICAL SCIENCES

POSTDOCTORAL RESEARCH OFFICER

Applications are invited for a Research Officer (funded by the Wellcome Trust) to study the sites and mechanisms of toxic effects of drugs on hearing Candidates should have experience of electrophysiological recording techniques and will ideally have a PhD in some aspect of auditory physiology

The appointment will be for one year initially with the possibility of renewal Commencing salary will be within the rang £7,520 to £8,920 per annum (under review).

Informal enquiries may be directed to Dr E S Harpur, extension 4180

Application forms and further particulars may be obtained from the Personnel Officer (Academic Staff), quoting Ref. 699/6, Aston University, Aston Triangle, Birmingham B4 7ET Tel 021 359 3611 Ext 4563. Closing date for receipt of applications is 19th July 1985. (6962)A

ROYAL POSTGRADUATE MEDICAL SCHOOL

(University of London)

DEPARTMENTS OF MEDICINE

(MRC Clinical Immunology Research Group) and Virology

A NON-CLINICAL LECTURER

is required to join the MRC supported group in the Department of Medicine This post will complement a group working on the pathogenesis and immunology of human cytomegalovirus (Dr J G P Sissons and colleagues) — which has a close liaison with the Department of Virology (Prof B Griffin). Candidates, who should be capable of conducting independent research, should have a background in virus molecular biology and be able to contribute to work on the molecular pathogenesis of cytomegalovirus infection.

Applications (6 copies) in the form of a cv with the names of three referees should be sent, together with a supporting statement of no more than 500 words, to the Deputy Secretary, Royal Postgraduate Medical School, 150 Ducane Rd, London W12 0HS from whom further particulars may be obtained.

Closing Date: 22 July 1985. (6957)A

BASIC SCIENTIST:

Assistant Professor of Surgery, Division of Urologic Surgery at the University of Cincinnati College of Medicine. Possible secondary appointment in appropriate basic science discipline. Candidates should have a Ph.D. degree, postdoctoral experience, and demonstrated ability in research (publications in peer-reviewed journals and research grants). Areas of research might include biochemistry, cell/molecular biology, or genetics. An interest in cancer is helpful; an interest in working closely with clinicians and clinically relevant problems in urologic surgery is a must

Send letter of interest, curriculum vitae, and names of three referees by September 15, 1985 to: Dr. H. Bruce Bosmann, Chairman, CSRP Search Committee, University of Cincinnati College of Medicine, ML #555, Cincinnati, Ohio 45267-0555.

The University of Cincinnati is an equal opportunity educator and employer. (NW1915)A

UNIVERSITY OF WISCONSIN-MADISON

Mycology/Microbial Ecology

RESEARCH ASSOCIATE (postdoctoral)

postition available 1 June 1985 on the BIOTECHNOLOGY and microbial ecology of fungal pathogens (biocontrols) to watermilfoil. Research aspects include mass culture and strain improvement techniques, interaction with other control measures, and tracking marked populations in water and sediment. Funding for two years. Salary competitive and commensurate with qualifications.

Send résumé with names of 3 referees to: Dr. John H. Andrews, Department of Plant Pathology, 1630 Linden Drive, Madison, WI 53706.

An affirmative action/equal opportunity employer. (NW1914)A

GRANTS & SCHOLARSHIPS

UNIVERSITY OF LEICESTER

DEPARTMENT OF CHEMISTRY

RESEARCH SCHOLARSHIP

Applications are invited for the above from graduates in Chemistry holding a first class honours or second class honours (upper division) degree. The successful candidate will be expected to undertake research in organometallic chemistry under the supervision of Dr D L Davies and to register for a higher degree The scholarship carries a maintenance award at the same level as SERC post-graduate studentships (£2,585 — under review). The University will waive registration fees.

Further details and application forms may be obtained from Professor Peacock, Department of Chemistry, University of Leicester, University Road, Leicester LE1 7RH, to whom completed applications should be returned by 31 July 1985. (6944)H

IMPERIAL CANCER RESEARCH FUND

BURSARY FOR TRAINING IN RESEARCH

Applicants are invited for an ICRF Bursarship tenable for 3 years from October 1985 for full time students leading to a higher degree in biochemistry The bursarship offers the opportunity to join an active cell membrane research group in the Department of Biochemistry, at the Royal College of Surgeons, in collaboration with the Cell Surface Biochemistry Laboratory, ICRF

The research topic, which will be jointly supervised by Professor N Crawford and Dr M Crumpton (ICRF), involves investigating procedures for permeabilising blood cells and their use as carrier vehicles with encapsulated drugs and other agents which activates macrophages for sustained tumouricidal effects.

Applications are invited from students, no more than 25 years of age on October 1st who hold, or expect to obtain a First or Upper Second Class Honours degree in Biochemistry or Cell Biology. The award carries a grant of £4,865 with possible additional allowances.

Further details and application forms can be obtained from: Miss S M Hurley, Personnel Officer, Imperial Cancer Research Fund, Lincoln's Inn Fields, London, WC2A 3PN

Please quote reference number. 85/85.

The forms should be completed and returned by 31st July 1985. (6904)H

Applications including curriculum vitae and names of two academic referees should be sent as soon as possible to Dr F C H Franklin, Department of Genetics, University of Birmingham, PO Box 363, Birmingham B15 2TT. Tel. No: 021-472 1301 Ext 2620. (6980)F

HERIOT-WATT UNIVERSITY
DEPARTMENT OF BREWING & BIOLOGICAL SCIENCES
RESEARCH STUDENTSHIP IN MICROBIAL GENETICS/ MOLECULAR BIOLOGY

A SERC Quote studentship is available in this Department tenable for three years and leading to a PhD. The project will involve the cloning and characterisation of genes for extracellular enzymes from thermophilic bacteria.

Applicants should hold a first or upper second degree in microbiology or a related discipline, and should send a curriculum vitae and names of two referees to Dr F G Priest, Department of Brewing & Biological Sciences, Heriot-Watt University, Chambers Street, Edinburgh, EH1 1HX. Closing date 4th July, 1985 (6965)F

UNIVERSITY OF SURREY
DEPARTMENT OF CHEMISTRY

Applications are invited from Chemistry graduates, or those about to graduate for the following research studentships which will become available as from 1st October, 1985.

1) A CASE studentship in conjunction with ICI Pharmaceuticaals to study
A THERMODYNAMICALLY-BASED SCALE OF HYDROGEN BOND BASICITIES
(Dr M H Abraham)

2) A CASE studentship in conjunction with the Imperial Cancer Research Fund to study
MECHANISMS OF AROMATIC HYDROXYLATIONS
(Dr J R Jones)

3) A CASE studentship in conjunction with ICI to study
THE SYNTHESIS OF POLYSULPHONES FROM ARYLSULPHONIC ACIDS AND PCl_5
(Professor J B Rose)

Interested persons should send their curriculum vitae and the names and addresses of two referees to Dr J R Jones, Chemistry Department, University of Surrey, Guildford, GU2 5XH, as soon as possible. (6978)F

QUEEN MARY COLLEGE
(University of London)
School of Biological Sciences
NERC POSTGRADUATE STUDENTSHIP

Applications are invited for a NERC Studentship to study the role of microfauna in the food webs of acid stream communities. A full curriculum vitae and the names of two referees should be sent, by 3rd July, to Dr A G Hildrew, School of Biological Sciences, Queen Mary College, Mile End Road, London E1 4NS. (6958)F

ROYAL POSTGRADUATE MEDICAL SCHOOL
(University of London)
(In collaboration with ICI Pharmaceuticals)
PhD STUDENTSHIP

In human cardiovascular pharmacology to study the humoral control of coronary artery tone in vitro using human material

Details from and applications to Dr R W Kerwin, Cardiovascular Unit, Hammersmith Hospital, 150 Ducane Rd, W12 0HS. Tel 01-743 2030 ext 690 (6956)F

UNIVERSITY OF NEWCASTLE UPON TYNE
DEPARTMENT OF CHILD HEALTH

Applications are invited for an MRC funded, three year
PhD STUDENTSHIP

to commence in October 1985 to investigate ketone body turnover in the neonatal period in man and experimental animals. The project will involve the use of stable-isotopically labelled substrares and gas chromotography — mass spectrometry. Candidates should have, or should expect to obtain, a First Class or Upper Second Class Honours Degree in Biochemistry or related subject.

Further details can be obtained from Professor A Aynsley-Green or Dr K Bartlett, Department of Child Health, The Medical School, The University, Framlington Place, Newcastle upon Tyne, NE2 4HH, to whom letters of application, including a curriculum vitae and the names of two academic referees, should be sent by not later than 12th July 1985. (6961)F

ST MARY'S HOSPITAL MEDICAL SCHOOL
(University of London)
Norfolk Place, London W2 1PG
SERC CASE STUDENTSHIP

Applications are invited for a SERC Case Studentship in collaboration with Shell Research Limited (Dr D H Hutson) for research (leading to a PhD degree) into the effect of environmental conditions on the metabolism of chemicals by fish

Applicants should have, or expect ot obtain, a first or second class honours degree in biochemistry, or chemistry, and have an interest in chemical and environmental toxicology

Applications, including the names and addresses of two referees, should be sent to the Assistant Secretary (Personnel) at the above address by 3 July 1985. For further details of the studentship contact Dr P Millburn tel no· (01) 723-1252 ext 118. (6907)F

UNIVERSITY OF NEWCASTLE UPON TYNE
DEPARTMENT OF INORGANIC CHEMISTRY

Applications are invited for an SERC sponsored Research Studentship leading to the degree of PhD, to investigate the synthesis of new polyoxometalates of early transition metals and their potential as ligands in organometallic chemistry. The project will involve a range of inert atmosphere, analytical, spectroscopic and electrochemical techniques The award will be tenable from October, 1985. Candidates should hold or expect to obtain a first or upper second class degree in chemistry Applications including a CV and the names and addresses of two referees should be sent as soon as possible to: Dr R J Errington, Department of Inorganic Chemistry, University of Newcastle upon Tyne, Newcastle upon Tyne, NE1 7RU from whom further information can be obtained (6926)F

UNIVERSITY OF LIVERPOOL
School of Dental Surgery
RESEARCH STUDENTSHIP

Applications are invited for a University Research Studentship for 3 years from October 1985 leading to a PhD degree Candidates should possess a first or upper second class honours degree in a biological science. The research project will be concerned either with disturbances of salivary function, involving in vivo and in vitro studies of secretory activity, or with calcification mechanisms in dental hard tissues using ultrastructural techniques Further details are available from Dr J Scott, Research Wing, Dental School (051 709 0141 extn 2973).

Applications together with the names of two referees should be received as soon as possible by the Registrar, the University, PO Box 147, Liverpool L69 3BX.

Quote Ref. RV/128/N (6968)F

Southampton THE UNIVERSITY
INSTITUTE OF CRYOGENICS
CASE RESEARCH STUDENTSHIP

Applications are invited for an SERC/British Gas CASE studentship to study instabilities in cryogenic liquids using LDA, microthermometer and flow visualisation techniques

Appy to: Professor R.G. Scurlock, Institute of Cryogenics, University of Southampton, Southampton SO9 5NH. (6928)F

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE
(University of London)
MRC RESEARCH STUDENTSHIP and MRC RESEARCH ASSISTANTSHIP GRADE (1B)

Applicants are invited for these two vacancies in a well-established group studying the immunology of schistosomiasis, with the main aim of producing molecular vaccines Both posts are tenable for three years from September 1st, 1985

The Research Studentship will be concerned with comparative studies on the immunology of Schistosoma mansoni and S japonicum, with emphasis on the identification of "protective" parasite antigens and cloning of the corresponding antigen genes. This work will be carried out in the Wolfson Unit for Molecular Medical Microbiology and Parasitology, and the person appointed, who must hold, or hope to obtain in 1985 a First or Upper Second Class Honours degree in Molecular Biology Microbiology, or Biochemistry will be registered for a PhD degree under the supervision of Dr Q D Bickle.

The Research Assistant will be working with Drs M G Taylor and Q D Bickle on antigen purification and the production of monoclonal antibodies, and studying the mechanism of immunity in vivo. Applications are invited from those who hold, or who are about to obtain, Honours degrees in relevant biological subjects. This 3-year appointment carries a starting salary of up to £7,055 per annum, plus £1,233 per annum London Allowance, and the appointee will be encouraged to register for a higher degree.

Applications, consisting of a full curriculum vitae and naming two referees, should be sent as soon as possible to the Personnel Office London School of Hygiene and Tropical Medicine, Keppel Street London WC1E 7HT.

Further information about the research to be undertaken may be obtained by telephoning Dr Taylor or Dr Bickle on St Albans 34201.

Closing date 8 July 1985 (6975)F

FELLOWSHIPS

The Wellcome Trust

Training Fellowships for research into mental disorders

Applications are invited from medical and scientific graduates who have worked in universities, institutes or hospitals in the United Kingdom or Eire for at least the past three years, or who did so before taking up an appointment overseas, for a fellowship for research training in the field of mental disorder.

These awards, which are tenable for up to three years, are intended for clinicians with a training in psychiatry, or intending to train in psychiatry, or postdoctoral scientists (with at least one year's postdoctoral research experience) who wish to extend their research experience The research proposals should be relevant to mental health or related basic science and the applicant should intend to continue research in this field. These fellowships may be held in appropriate departments or clinical centres in Great Britain In cases where the necessary research training cannot all be obtained in Great Britain, the Trustees are prepared to consider a request that part of a fellowship be spent in a suitable centre or centres abroad.

Candidates should not normally be over 32 years of age for science graduates and 34 years for medical graduates. Applications should be made by the Head of the Department in which the candidate proposes to work. Salaries will be in the range of University Lecturer scales according to age and experience

Application forms can be obtained from: The Grants Section, The Wellcome Trust, 1 Park Square West, London, NW1 4LJ. Telephone: 01-486 4902. Applications must be returned by the 1st September 1985.

The Wellcome Trustees are concerned that research careers of outstanding young clinical and non-clinical scientists should not suffer from lack of suitable support and guidance at any stage. Exceptional candidates proposed for the above fellowships may be considered at a later date for senior fellowships which will provide additional support at a later stage in the fellow's career (not necessarily immediately after the training fellowship) to advance the fellow to a stage where he or she is ready to apply for senior research and academic positions.

(6986)E

The John Hopkins University
Department of Anesthesiology and Critical Care Medicine

POST DOCTORAL FELLOWSHIP IN RESEARCH

Applications are invited for this position available immediately to study the molecular biology of human cytochrome P450 The applicant must be creative and highly motivated to carry out independent experimentation utilizing human cytochrome P450 under study

M D or Ph D required with 1–2 years experience in molecular biology

Contact: Roy C. Levitt, M.D., The John Hopkins University, Department of Anesthesiology and Critical Care Medicine, Blalock 1410, Baltimore, Maryland 21205. Telephone (301) 955-7609. (NW1822)E

STUDENTSHIPS continued

THE ROWETT RESEARCH INSTITUTE
Bucksburn, Aberdeen, AB2 9SB

SERC CASE STUDENTSHIP

DEPARTMENT OF CHEMISTRY (AGRICULTURE), GLASGOW UNIVERSITY
Rowett Research Institute, Aberdeen

Applications are invited for a studentship to investigate the nature of lignin-carbohydrate linkages in straw The project should lead to a clearer understanding of how cell-wall structure determines the digestibility not only of straw, but also grass and other forage crops, in ruminants, and how digestibility can be improved by processing Experimental work will involve the use of advanced gas and liquid chromatography, NMR, mass spectroscopy, enzyme digestion and other techniques

The student will register for a PhD degree at Glasgow University, but is expected to spend only about one year there in total, the remaining period will be spent at the Rowett Institute. In addition to a first or good second class honours degree or equivalent, the main requirement is a sound grasp of analytical techniques and an interest in their applications to biological systems. Some knowledge of animal nutrition and plant composition would be helpful but is not essential

Applicants should send a CV and the names of two referees as soon as possible to, The Secretary, Rowett Research Institute, Bucksburn, Aberdeen, AB2 9SB. Tel: 022 – 712751 Ext. 338

Closing date 18th July 1985.

(6916)F

UNIVERSITY OF BIRMINGHAM

FACULTY OF MEDICINE AND DENTISTRY

DEPARTMENT OF HAEMATOLOGY

Applications invited for a 2 year Leukaemia Research Fund training fellowship in the joint University/NHS department of Haematology at the University of Birmingham and Queen Elizabeth Hospital The post would suit a medical graduate with MRCP qualification, and previous experience at Registrar level in Haematology Clinical and Laboratory training will be offered in the management of haematological malignancies and in Bone Marrow Transplantation A major research project will be undertaken and the successful candidate will be expected to register for a PhD or MD at an appropriate University Honorary registrar status will be sought from the Central Birmingham Health District. Salary in scale Research Fellow Clinical. Maximum starting £10,640

Applicants are invited to visit the department by arrangement with Dr B J Boughton, Senior Lecturer in Haematology (telephone 021 472 1311 ext 177) Applications (3 copies) to Assistant Registrar, Medical School, Birmingham B15 2TJ from whom further particulars are available by 14 July 1985, Quote Ref: RFC/HAE/BJB

(6932)E

CANOLFAN ASTUDIAETHAU TIROEDD CRAS COLEG PRIFYSGOL GOGLEDD CYMRU
UNIVERSITY COLLEGE OF NORTH WALES CENTRE FOR ARID ZONE STUDIES

THE YAMANI FELLOWSHIPS

His Excellency Sheikh Ahmed Zaki Yamani has generously endowed Fellowships within this Centre.

The recipients must be from Arab or Third World Countries and should contribute to the teaching and research within the Centre. Tenure may be from 3 months to 1 year.

The Centre has wide interests in the development of Agriculture and Forestry in arid and semi-arid areas and in allied scientific and environmental problems.

Support can be given for subsistence and travel costs and for experimental work.

Further details from: Professor R G Wyn Jones, Centre for Arid Zone Studies, University College of North Wales, Bangor, Gwynedd.

Applications (two copies), giving details of age, education and experience, together with the names and addresses of two referees, should be sent to the Personnel Office, University College of North Wales, Bangor, Gwynedd LL57 2DG (6942)E

THE IZAAK WALTON KILLAM

POSTDOCTORAL FELLOWSHIPS

FOR 1986-87

Value

Fellowships valued at $22,500 (1985-86, plus travel allowances, are tenable for one year at Dalhousie University in most fields of study. Application for extensions may be considered.

Qualifications

Applicants should have recently completed a Ph.D. degree at a recognized university, or expect to obtain a degree before taking up an award.

Application

Application forms may be obtained by writing to:

The Office of the Dean
Faculty of Graduate Studies
Dalhousie University
Halifax, Nova Scotia B3H 4H6

The closing date for receipt of applications is 15 December 1985. (NW1898)E

UNIVERSITY OF BIRMINGHAM

FACULTY OF SCIENCE AND ENGINEERING

DEPARTMENTS OF CHEMICAL ENGINEERING AND PLANT BIOLOGY

POSTDOCTORAL RESEARCH FELLOWSHIP AND RESEARCH ASSOCIATESHIP

Applications are invited for (a) a Postdoctoral physical/colloid chemist and (b) a graduate chemical engineer or biologist preferably with experience in biotechnology or bioengineering.

The project is a co-operative research grant funded by the SERC and is concerned with the development of novel polymers for the prevention of biofilm adhesion in process plant. The persons appointed will join groups working on biofouling (Dr T Bott, Chemical Engineering and Dr M E Callow, Plant Biology) and surface chemistry (Dr J Goodwin, Physical Chemistry, Bristol University). Co-operating bodies are International Paint plc and APV International Ltd.

Post tenable for up to three years from 1 September 1985.

Salary on the Research Fellow scale £7,520—£12,150 plus superannuation Salary on the Research Associate scale £6,600—£8,920 plus superannuation.

For further information, phone 021-472-1301 ext. 2559 quoting reference T9

No formal application form. Three copies of application, including full curriculum vitae and naming three referees to Assistant Registrar (Science and Engineering), PO Box 363, Birmingham B15 2TT by 15th July, 1985. (6931)E

EMBO

EUROPEAN MOLECULAR BIOLOGY ORGANIZATION

SHORT TERM FELLOWSHIPS

in molecular biology

The European Molecular Biology Organisation awards, to scientists working in Europe and Israel in the field of molecular biology and allied disciplines, short term fellowships of one week up to three months duration The fellowships are to support collaborative research between laboratories in different countries and provide a travel grant and subsistence allowance Applications may be made at any time and are decided upon soon after the receipt of application

Applications for exchanges between laboratories within any one country cannot be considered Fellowships involving transatlantic travel are awarded only in extremely exceptional circumstances

Application forms and further details may be obtained from Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, 69 Heidelberg 1, Postfach 102240, F.R.G. (W1577)E

POSTDOCTORAL FELLOWSHIP IN MOLECULAR BIOLOGY/ BIOCHEMISTRY

Position available in Department of Microbiology at Suny Stony Brook to study Adeno-associated virus genetics, vector construction, immunology or DNA replications. **Send CV and references to Dr Nicholas Muzyczka, University of Florida, College of Medicine, Box J226 JHMHC, Gainesville, FL 32610** (NW1901)E

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE (University of London)

DEPARTMENT OF BIOCHEMISTRY AND CHEMISTRY

JUNIOR RESEARCH FELLOWSHIP

Applications are invited from graduates or students obtaining a good honours degree in Biochemistry or related subjects for a three year junior Research Fellowship, starting on 1 October 1985. The successful candidate will register for a higher degree in the University of London The project concerns the mechanisms of polyphosphoinositide metabolism and arachidonic acid release in endocrine cells. The conditions of employment and salary are similar to the SERC/MRC studentships.

A curriculum vitae and the names of two academic referees should be sent to Professor B A Cooke, Department of Biochemistry and Chemistry, Royal Free Hospital School of Medicine, Rowland Hill Street, London, NW3 2PF. Telephone 01-794-0500 extension 4202 (6959)E

ASSOCIATESHIPS

UNIVERSITY OF LEICESTER

DEPARTMENT OF CHEMISTRY

POSTDOCTORAL RESEARCH ASSOCIATESHIP

Applications are invited for a postdoctoral research associateship supported by the SERC, to study phosphoryl transfer reactions including enzyme catalysed reactions Some experience of synthesis and an interest in reaction mechanism is desirable. The appointment will be for two years (start 1 October 1985). The starting salary will be in the range £7,520—£8,920 pa

Applictions with curriculum vitae and names and addresses of at least two referees should be sent, not later than 31 July, to Dr P M Cullis, Department of Chemistry, The University, Leicester LE1 7RH. (6953)O

ASSISTANTSHIPS

THE SCHOOL OF PHARMACY UNIVERSITY OF LONDON

DEPARTMENTS OF PHARMACEUTICAL CHEMISTRY AND PHARMACOGNOSY

POST-DOCTORAL RESEARCH ASSISTANT

Applications are invited for a SERC funded postdoctoral research assistantship to investigate "Novel phorbol esters and their interaction with protein kinase C". This multidisciplinary research post would be suitable for someone with experience in biochemistry and natural product chemistry and will be available for up to 3 years.

The project will involve the study of tumour promoting and inflammatory diterpenoid derivatives (phorbol esters) that stimulate the activity of an enzyme (protein kinase C) implicated in the control of a wide range of cellular activities.

The person appointed will work with members of staff in departments that have excellent facilities for research in natural product chemistry, biochemistry and molecular biology

Further details may be obtained from Dr Alastair Aitken (Dept of Pharmaceutical Chemistry) and Dr F J Evans (Dept pf Pharmacology) on 01 837 7651

Applications, including 2 copies of CV and names of 2 referees, to be sent to: Personnel Officer, The School of Pharmacy, 29/39 Brunswick Square, London WC1N 1AX, to arrive within 4 weeks of the advertisement (6976)P

DURHAM UNIVERSITY

DEPARTMENT OF CHEMISTRY

Applications are invited for a postgraduate

RESEARCH ASSISTANTSHIP

tenable for 3 years from 1 October 1985 or as soon as possible thereafter to work with Dr D Parker on the chemistry of functionalised macrocycles. Applicants should have at least a 2(i) Honours Degree in Chemistry and will be expected to register for a higher degree. The project involves the development of selective lithium ionophores with a concurrent investigation of the chemistry of heterodinuclear complexes.

Applications (3 copies) naming 3 referees should be sent by 5 July to The Registrar, Science Laboratories, South Road, Durham DH1 3LE, from whom further particulars may be obtained. (6943)P

APPOINTMENTS WANTED

advertise your qualities and qualifications through the most influential science weekly in the world at a special reduced cost of $8 per line. (Personal Box Numbers $10.00). Advertisements must be pre-paid and sent to: Nature Classified (Appts Wtd), 65 Bleecker Street, New York, NY 10012. (890)B

CONFERENCES & COURSES

ATTENTION SCIENTISTS AND RESEARCHERS

Posters are now being accepted for BIO/TECHNOLOGY's premier conference

BIO/TECHNOLOGY

LOOKS TO THE NEXT DECADE

January 20-22, 1986, Clarion Hotel, New Orleans

You are invited to submit abstracts of work with commercial implications to:

Research Editor
BIO/TECHNOLOGY Conference
65 Bleecker Street, New York, NY 10012

Ideas suitable for support from corporate or venture funding are particularly welcome.

Conference Themes:
Day 1: The Molecular Biology of Plants & Animals
Day 2: Commercial Production Processes
Day 3: Innovations in Pharmaceuticals & Immunology

UNIVERSITY OF LIVERPOOL

OCEANOGRAPHY DEPARTMENT

POSTGRADUATE DIPLOMA IN MARINE POLLUTION CHEMISTRY

This six month course is designed to provide scientists having a chemical background with training in Marine Chemistry, Marine Pollution Chemistry and Analytical Chemistry applied to marine problems.

Participants will gain a working knowledge of estuarine, coastal and marine pollution with particular respect to the identification, monitoring and control of individual pollutants.

The course has a strong emphasis on practical work in the laboratory. The course is open to applicants of all nationalities and some NERC funding may be available for suitable British candidates.

The next course starts in January 1986

Further information and application forms may be obtained from Dr M R Preston (MPC), Oceanography Department, Liverpool University, PO Box 147, Liverpool, L69 3BX. (6952)C

Please mention nature

UNIVERSITY OF ABERDEEN

DEPARTMENTS OF THERAPEUTICS AND CLINICAL PHARMACOLOGY AND PHARMACOLOGY

MSc STUDENTSHIP

There are several studentships available for the MSc Clinical Pharmacology course. This course consists of lectures and practical work in addition to an original research project and is designed for graduates with appropriate qualifications in Pharmacology, Pharmacy, Biochemistry, Medicine or a related subject who wish to work in this field.

There are also three research studentships, initially for one year, to investigate:

1) cryopreservation of human hepatocytes for drug toxicity studies.

2) mechanisms of drug induced toxicity using isolated proximal tubular cells.

3) polyamine metabolism in human breast cancer cells.

Further details may be obtained from Dr G M Hawksworth, Department of Therapeutics and Clinical Pharmacology, University Medical Buildings, Foresthill, Aberdeen, AB9 2ZD, (0224 681818 Ext: 2463) to whom application, including the names and addresses of two academic referees, should be sent as soon as possible. (6941)C

Royal Postgraduate Medical School

(University of London)

A specialist scheme of study for medicine, veterinary or science graduates leading to the award of:

DIPLOMA IN ENDOCRINOLOGY

This is a one academic year, full-time intensive laboratory-based training course open to those with a medical, veterinary or scientific qualification who wish to develop skills in modern endocrinological investigative methods. The selected applicants will undertake a series of research projects broadly based on the investigation of regulatory peptide endocrinology. Award of the **Diploma** will depend on the successful completion of an examination or by thesis.

Candidates may register for one of two recognised schemes of study:

Diploma in Endocrinology (Pathology)

Application for entry is open to graduates who have some training in histopathology. The selected applicants should preferably have experience in light or electron microscopical morphology. Supervisor: Professor Julia M. Polak (Endocrine Pathology).

Diploma in Endocrinology (Biochemistry)

Application is open for clinicians or science graudates with an endocrinology background. Applicants should, if possible, have some experience of laboratory techniques Supervisor: Professor S.R. Bloom (Endocrinology).

Further details and application forms may be obtained by writing to:

The School Office,
Royal Postgraduate Medical School,
Hammersmith Hospital,
Du Cane Road, London W12 0HS.

Completed application forms must be received before 31st July 1985 for registration on the 1985/1986 Diploma course. (6939)C

ADVANCED COURSE IN FLOW CYTOMETRY: ANALYSIS AND FLOURESCENCE ACTIVATED CELL SORTING

Paris, September 9-14, 1985

Sponsored by: The Cancer Research Association (ARC) — Jaques Crozemarie, President, and the "Centre Technique pour le soutien de la Recherche sur le Cancer des Laboratories et Formations du Centre National pour la Recherche Scientifique" (C.N.R.S.)

A Course in Flow Cytometry will be offered with special emphasis on cell biology. Themes will include Multiparameter cell sorting, cell lineage studies, tumor cells characterization, gene amplification selection, cloning of genes by transfection, somatic cell genetics, hybridoma variant selection, liposome endocytosis, cell cycle analysis. Brd U and cytokinetic studies, mathematical modeling of the cell cycle, computer system for multiparameter data analysis, cytochemistry and new fluorochromes, karyotype analysis, pumped dye lasers, emission anisotropy.

The Course will consist of lectures, laboratory demonstrations and problem solving sessions

Course Directors: Harry Crissman (Los Alamos National Laboratories), Claude Rosenfeld (INSERM, Villejuif, France)

Organizers: L.A. Herzenberg (Stanford University, USA), P. Le Bouteiller (Centre dimmunologie de Marseille-Luminy, France), Z. Mishal (C N.R.S., Vilejuif, France), M. Monsigny (Centre de biophysique moléculare, Orleans, France), J.L. Roti-Roti (Washington University of St. Louis, USA).

Lecturers will include the above plus: B. Bagwell, S. Cram, Z. Darzienkiewicz, P. Dean, M. Goldberg, J. Gray, P. Horan, C Julien, M. Loken, P. Manoni, H S Micklem, K. Muirhead, D.R. Parks, A. Truneh.

Course tuition: $500 (5 000 FF) includes laboratory fees, manual, coffee breaks, lunches and an optional Flow Cytometry Certificate.

Send C V. and tuition deposit $50 (500 FF) to the local Course Director (max 50 persons).

Dr. Claude Rosenfeld,
INSERM Unite 253,
Groupe Hospitalier Paul Brousse,
16 bis avenue Paul Vaillant Couturier,
94804 Villejuif, France.

Application deadline June 30 1985, priority given to early applicants (W1919)C
